Mr. BRYANT, proceeding, said if they established a sinking fund it would work out in this way. If they put the fund into the hands of the Government they would receive interest at the rate of only 2½ per cent. per annum and in fifty years that would come to only £20,958. That was less by £4000 than they would get from the Alliance Insurance Company for the same annual payments, because for £215 the Alliance Insurance Company at the end of 50 years would give them £25,000. He had examined the terms which they might get from the Rock Insurance Company and he found that they were not so favourable. There was a suggestion that the insurance might be effected by the payment of a lump sum. If they accepted that suggestion the English Branch Council would be prepared to advance the necessary money, £5700, and would ask on it interest at the rate of only 3 per cent., which meant that the Council would require to pay annually only £171 or £44 a year less than if they were to pay over the sum in fifty instalments of £215 each. He conceived that this annual payment of £171 would not be felt by the Council, and if at any time in the future the Council felt pinched they could get the money back from the insurance company at the rate of 3 per cent. simple interest. He moved that the president and treasurer should be authorised to start a sinking fund to repay the English Branch Council the sum of £25,000 at the end of fifty years, either by the payment of a lump sum or by annual payments.

Sir DYCE DUCKWORTH seconded the motion.

Mr. BROWN earnestly appealed to Mr. Bryant to postpone this question till May next. He maintained that there was no hurry. The scheme now brought before the Council was something novel and he must remind them that there was a great deal of difference in regard to this matter in all the Branch Councils.

Mr. TOMES suggested to Mr. Bryant that he might propose a motion establishing the principle and give the Council an opportunity of examining the details.

Mr. BRYANT thereupon proposed the establishment of a sinking fund by one payment of £5700.

Sir CHRISTOPHER NIXON opposed altogether the idea of the establishment of a sinking fund for the reason given in the report of the Irish Branch Council. In the forty years the Council had been in existence the English Branch Council had been able to accumulate no less than £40,000, while the Irish Branch Council had not a sixpence. That the latter was so poor did not much matter to the Council itself because the General Council was bound to provide for the expenses of the Irish Council. Perhaps it was a pity that the original arrangements should have permitted this, and if there was to be any legislation which would alter the conditions of the Medical Act, one thing he should ask for would be that there should be a common fund.

Dr. ATTHILL said that the General Medical Council had on loan from the English Branch Council between £20,000 and £30,000 at the rate of 2½ per cent. and they were no losers. Why they should wish to get this money repaid seemed to him to be an extraordinary thing. Apart from that, supposing they established the suggested sinking fund, what was the benefit to be to the Council in the future? Fifty years hence what would they do? If they got this money returned to them they would need to invest it. So far as the Irish Council was concerned he, as a member of it, would oppose this motion on business grounds. In 1895 the Irish Council had some £800 or £900 to the good, but in 1896 they entered upon the down grade, and if they were required to pay as much to the General Council as they had been called upon to do during the last few years he believed that next year the Irish Council would become bankrupt unless they got back some of the money derived from the sale of the new edition of the Pharmacopœia.

Mr. BROWN, rising again, said that the question was not in such a condition as to enable the Council to come to a decision that day and he therefore moved that the matter should be referred back to the Branch Councils for consideration and report.

Dr. BRUCE seconded this proposal.

Dr. MACVAIL said that the Scottish Branch Council approved of a scheme which would enable the buildings of the Council to become the property of the General Council itself and not of any Branch Council. He hoped that the Council would now approve of the principle of a sinking fund.

Dr. HERON WATSON felt sure that the Council would agree in general terms to the principle of a sinking fund, but it was evident that the schemes which had been mentioned had not been fully considered, and it seemed to him that before proceeding further they should have an actuarial report.

Dr. GLOVER agreed. They should get the report of an expert who was altogether independent of insurance offices.

Mr. BRYANT said that he had no objection to take the matter back in order to obtain an expert's report.

After some further discussion it was agreed, on the motion of Mr. BRYANT, seconded by Sir DYCE DUCKWORTH:—

That the Council approve of the proposal to form a sinking fund to repay the English Branch Council at the end of a term of years the sum of £25,000, and that the Finance Committee be authorised to obtain from an expert a report, to be laid before the Council, upon the methods of carrying the proposal into effect.

Inspector of Examinations.

Sir DYCE DUCKWORTH presented a report from the Executive Committee in regard to the resignation of Dr. Sidney Coupland, the inspector of examinations, and moved that Sir George Duffey be appointed in his stead.

Mr. BRYANT seconded.

Dr. BRUCE moved, as an amendment, that the question of the appointment of an examiner be referred back to the Executive Committee with power to make an appointment. Sir George Duffey was a friend of his, but he thought that the appointment it was proposed to give him would not be a wise one. Sir George Duffey had been an examiner under the old conditions of the Dublin Apothecaries' Company and it might be well that he should not be appointed under the arrangement which now existed.

Dr. REID seconded the amendment.

Dr. ATTHILL agreed that it might be as well they should get a new man. Sir George Duffey was certainly an able

Digitized by Google

man but he had not sought this appointment and he did not know that he wanted it.

Dr. MACALISTER pointed out that they all had the fullest confidence in Sir George Duffey and even though the amendment were carried that must not be taken as casting any reflection whatever upon that gentleman.

Mr. TICHBORNE did not think the appointment of Sir George Duffey would be acceptable to the Dublin Apothecaries' Hall, because he was associated with a body which was competing with the Hall. He questioned very much if Sir George Duffey would accept the appointment if he got the opportunity of taking it up.

The amendment was agreed to, the PRESIDENT pointing out that the Executive Committee at the end of the Council's sitting could meet for the purpose of making an appointment. Thereafter the following resolutions were adopted—namely:—

That the inspector be appointed to inspect all the examinations of the Apothecaries' Hall, Dublin.

That the inspector also be appointed to inspect the Conjoint Examinations of the Royal College of Surgeons in Ireland and the Apothecaries' Hall, Dublin.

That the remuneration assigned to him be on the same scale as that to Dr. Coupland.

That the Council do authorise the President to nominate one or more members of the Council to act as visitors along with the inspector.

Irish Examinations.

Mr. TICHBORNE proposed:—

That the examinations of the Conjoint Board of the Royal College of Physicians and the Royal College of Surgeons, Ireland, be reported upon for the next year by the inspector and visitor appointed by the Medical Council.

He stated that the reason why he proposed this motion was that the examinations of the Conjoint Board were not only not up to the standard of the Conjoint Board for the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Dublin, but were below the standard required by the Council.

Dr. BRUCE seconded the motion.

Sir CHRISTOPHER NIXON proposed as an amendment:—

That the examinations of the Royal College of Physicians and the Royal College of Surgeons of Ireland be reported upon only at the same time as the report of the examinations of the universities and licensing corporations in general are presented to the Council.

He supposed this motion by the representative of the Dublin Apothecaries' Hall had been inspired simply out of spite because of the frequency with which the inefficiency of the Hall had been brought before the notice of the Council. He thought the hands of the Dublin Hall authorities were at present full enough with their own affairs instead of interfering with those of other bodies. There was no evidence before the Council that the conjoint examination of the Irish Royal Colleges of Physicians and Surgeons was not up to the standard required by the Council and consequently it would be an ungracious act on the part of the Council to interfere with these examinations.

Sir WILLIAM THOMSON, who seconded the amendment, agreed that no case had been made out to justify the motion.

Dr. MACALISTER pointed out that if the motion were carried they would be proceeding contrary to the Standing Orders.

On a show of hands 17 voted for the amendment and 2 against.

The PRESIDENT thereupon proposed to put the amendment as a substantive motion.

Dr. MACALISTER said he could not vote for it. There was no need to adopt Sir Christopher Nixon's proposal and they should take care to keep in their own hands, unfettered by any such proposal, the times at which they should examine any of the licensing bodies.

On a division only 7 voted for the substantive motion, which accordingly was rejected by a majority.

Alleged Recognition of Grammar School Studies by the London Colleges.

Sir PHILIP SMYLY called attention to the following letter forwarded by the Royal College of Surgeons in Ireland in regard to a regulation of the Conjoint Board of the Royal Colleges of Physicians of London and Surgeons of England, which accepts time spent in institutes recognised by it for instruction in physics, chemistry, practical chemistry, and biology as the first of the five years of professional study:—

SIR,—The attention of the President and Council of this College has been called to the terms of a regulation promulgated by the Conjoint Examination Board of the Royal Colleges of Physicians and Surgeons of England on the 14th of July, 1898, which declares that "the first of the five years of professional study may be spent at an institute recognised by the board for instruction in chemistry, physics, and practical chemistry and biology, or six months may be spent in attendance at a similar institution in receiving instruction in chemistry, physics, and practical chemistry only." Four complete years of professional study must be attended at a recognised medical school and hospital after passing parts i. and iii. of the first professional examination.

It is furthermore observed that, as appears from the most recent list of "institutions" recognised by the London Conjoint Board, 54 non-medical schools are accepted as centres of study in these subjects, of which 35 are grammar schools and the remainder are departments of local technical schools, the teaching capacity of which may be open to question.

This College submits that the above quoted regulation of the London Conjoint Board, which declares that four years of medical study shall suffice for a grammar school boy or a student of a technical school, while five years are required from a student of a medical school, is at variance with the recommendation of the General Medical Council of June 9th, 1896 (Minutes, vol. xxxi., p. 163), which explicitly declares that "such course or courses shall not be held to constitute any part of the five years' course of professional study." When the General Medical Council adopted the requirement it declared that such course should only qualify for part of the first year's examination, but should not under any circumstances exempt the student from any part of his five years' course of professional study; yet the London Conjoint Board has granted exemption from the first year in respect of the courses and has thus reduced the necessary period in the cases of these students to four years.

This College observes that, so far as the General Medical Council has recognised studies in non-medical schools, it has done so under guarantees for the *bonâ-fides* of the instructions therein and has reserved to itself by implication the power to withhold recognition. In 1894 (Minutes of General Medical Council, p. 162) it resolved to require a list of institutions to be submitted by the licensing body which proposed to recognise them, and also required that a statement should be appended by such body "that after due inspection it is satisfied that the institution so recognised possesses sufficient laboratory accommodation and appliances for the efficient teaching of the required subjects." This College is unable to discover from the official records of the General Medical Council that the London Colleges have ever presented any statement as to the requisite inspection of such schools or as to their satisfaction with the teaching arrangements, or that if such statement were presented it was ever laid before the Council or received their approval. Notwithstanding this, it is observed that certain of these grammar schools and technical schools have been inscribed in the Students' Register as "institutions," the studies in which are accepted as the "commencement of medical study," and this College is desirous of being informed of the grounds on which such acceptance has been accorded, inasmuch as no permission is to be found in the records of the Council.

I am directed by the President and Council of this College to submit to the General Medical Council their most earnest protest against the recognition of grammar schools or other unguaranteed "institutions" as centres whose teaching exempts students from their first year of professional study, and to point out that their protest is supported by the emphatic judgment of the Education Committee of the General Medical Council (see Minutes, vol. xxx., Appendix 16, pages 8 *et seq.*). That judgment declares that the "interpretation of the phrase 'teaching institution' so as to include ordinary public schools was not contemplated by the Council," and was, in fact, rejected by the Council, and that "the intention of the Council was that the first years should, in general, be passed, if not at a university or other school of medicine, at a recognised school of science or technical college where the student could be brought under influences which are not operative in the school-room.

Under these circumstances the President and the Council of this College submit the requests:

1. That no centre of teaching shall be in future recognised as qualified to certify the "commencement of medical study" save a university or a recognised school of medicine, or a school of science in respect of which evidence of "inspection" and of "accommodation and appliances for the efficient teaching of the required subject" shall have been presented to the Council.
2. That all centres of teaching not included in this category be removed from the list in the Students' Register.
3. That except in the case of institutions thus indicated all students shall be required to fulfil the complete course of five years of professional study, exclusive of all studies pursued before the legitimate commencement of medical study. Or also
4. That for all students whomsoever the requisite course shall be in future reduced to four years.

I am, dear Sir, yours obediently,

JOHN BARTON, F.R.C.S.,

Secretary of Council, Royal College of Surgeons in Ireland.

The Registrar of the General Medical Council, Nov. 17th, 1898.

He (Sir Philip Smyly) had put on the programme notice to move the four requests of his College as four separate and distinct motions and Sir William Thomson proposed to second him. The Irish College of Surgeons had prepared their letter very carefully and they did not wish it to be taken as an attack upon either the English Conjoint Board or the English Royal Colleges. The Council had power to express an opinion and issue a recommendation and he could promise on the part of his College that any recommendation of theirs would be received with all due loyalty and respect.

The letter, which was read at length, was entered on the minutes. Thereupon

Sir PHILIP SMYLY proposed the first of the four resolutions standing in his name.

Sir WILLIAM THOMSON, in seconding the motion, contended that while the Council's recommendation was that there should be a five years' course of study in professional subjects subsequently to the passing of the preliminary

Digitized by Google

examination the regulation of the English Conjoint Board reduced the period of professional study to four years. The English Conjoint Board had therefore departed from the Council's policy of a five years' *bona fide* medical curriculum, dating from registration in the Students' Register. He did not question the capability of grammar schools to give general education, but he questioned the power and capacity of grammar schools to give the first year's medical instruction, and it was impossible that they could take even from South Kensington an opinion that such and such a school was suitable to teach the subjects prescribed for the first year of medical study.

Mr. BRYANT admitted that the Royal College of Surgeons of England had in a measure, but only to a slight degree, deviated from the recommendations of the General Medical Council, but they believed that the deviation was in the direction of improvement rather than the reverse. Members knew that the Council for many years had sanctioned outside institutions as teaching institutions for the medical preliminary subjects. The College of Surgeons had now done the same and the success which had attended their action had not been a bad one, for statistics showed that of the successful candidates 67 per cent. came from the outside institutions, as compared with 61 per cent. from the medical schools. Therefore the Conjoint Board scheme had not been to the detriment of the medical schools. It had been the experience of all—teachers and examiners alike—that the preliminary subjects often ran over into the second year, sometimes into the third. So that they said to those students who had not been able to qualify in parts i. and iii., if their study required to extend into the second year, "You have still to pass full four years of professional work before you are admitted to the profession of medicine and surgery." Although his College had not followed quite in the lines which the General Medical Council had recommended they had recognised the principle involved in the recommendation. He was willing to admit that perhaps they had been too liberal in recognising the institutions recognised by South Kensington. At the same time he had to say that during the past year or two they had visited those institutions of which they had any doubt. They had always had good visitors to inspect these places and where there had been the shadow of a doubt the institutions had not been accepted. He moved that the communication from the Irish College of Surgeons and the motions based thereupon standing in the names of Sir Philip Smyly and Sir William Thomson should be referred to the Education Committee for consideration and report.

Sir CHRISTOPHER NIXON, in seconding this proposal, congratulated Mr. Bryant on the frank acknowledgment he had made on the part of the College of Surgeons that they had deviated from the recommendations of the General Council. The body he represented—the Royal University of Ireland—received intimation of the English Conjoint Board's action with consternation, and it was felt that the English Board had by that action rather stolen a march upon the universities. If the Council allowed all the licensing bodies to recognise the grammar schools of the country they were putting the universities to a disadvantage. There was no doubt that advantage accrued from having medical students trained in medical schools which had always been inspected and contained proper appliances for the necessary tuition.

Sir DYCE DUCKWORTH said that the English Conjoint Board was very well satisfied with the results attained under their new regulation. It had been the experience of teachers and examiners that a large proportion of the failures in examinations resulted from the mixing up of tuition in general and professional subjects. The new arrangement enabled an ordinary intelligent student to begin his professional studies during school life, and the Royal College of Physicians of London saw no harm in that. The University of London was perfectly satisfied with the arrangement. The Scottish universities, he believed, had a similar arrangement.

The PRESIDENT said that that was a mistake. A candidate for the medical profession must study in the university or in a recognised medical school. Repeatedly application had been made to the University of Edinburgh for the recognition of institutions in the rank of grammar schools, but they had always been declined. It was as well to mention that fact, for in the debate in the Royal College of Physicians of London the Scottish universities had been placed in an entirely wrong position by one of the speakers and he was desirous to correct the erroneous impression.

Sir DYCE DUCKWORTH remarked that some of the technical schools were really equivalent only to grammar schools and it came to be a question of the relative value of the teaching. It was quite certain that some grammar schools and some other institutions recognised by the Conjoint Board were distinctly better teaching institutions than many of the medical schools, the teachers and the standard of the teaching being distinctly higher in these outside institutions than in the medical schools. Therefore it could not be supposed that students trained in these outside institutions were losing ground. The Conjoint Board allowed no student to pass into the profession who had not undergone five years of professional study. The arrangement which they had made they considered was the best way of meeting requirements.

Mr. BROWN said that as a Direct Representative for England he owed a debt of gratitude to the Irish members for calling attention to this matter. They had been told by Sir Dyce Duckworth that many grammar schools and other teaching institutions recognised by the Conjoint Board could give a professional education better than many of the medical schools. That was an important statement which he hoped would receive attention in the proper quarter. He did not dispute that it was so but there were members of this Council who thought that the recognition of grammar schools by the Conjoint Board was an attempt to get behind the regulations of the General Medical Council. To some extent it had been successful, for it supplied not what the London medical schools supplied but what the Irish and Scotch schools did supply. He objected to the acknowledgment of grammar schools in the neighbourhood of London and he hoped they would be able to thrash the whole subject out next session. The grievance was by no means a bogey one but a real grievance.

Dr. BENNETT held that the regulation in question really instituted a four instead of a five years' professional curriculum.

Dr. HERON WATSON contended that the action questioned was in accordance with the action of the Royal College of Surgeons of England with reference to dental education. It evaded the spirit if not the letter of the General Medical Council's recommendation. Their answer in this instance was precisely of the same character and bore the same interpretation as on dental education. The Council had better keep their eyes open as to what the Royal College of Surgeons of England was inclined to do.

Sir JOHN BATTY TUKE, as chairman of the Education Committee, said that he and he had no doubt his colleagues also on the committee would undertake with pleasure the duty of reporting on the subject if the Council cared to pass the amendment, but he must tell them that he could not see that the committee could do other than reaffirm their decision that the curriculum should be a full five years' one.

The amendment proposed by Mr. BRYANT was then carried by a large majority and became the finding of the Council.

Inspection of Documents.

Sir RICHARD THORNE moved:—

That in view of the fact that the operation of the Standing Orders as to the inspection of documents passed by the Council on May 31st, 1898, is not altogether satisfactory the Executive Committee be instructed to consider and report to the Council at the next session: What arrangements can be best made to facilitate that examination by members of the Council of all documents which are the property of the Council, subject to leave being obtained for such examination, and to the legal rights of the Council in regard to such documents, as also to their proper safeguard.

Dr. MACALISTER seconded the motion.

Mr. HORSLEY moved to leave out the words providing that inspection should be subject to leave being obtained. He said he had legal advice that it was not necessary to obtain leave, the rights of all members of the Council in respect to Council documents being equal.

Mr. TOMES seconded Mr. Horsley's proposal.

Dr. MACALISTER said that the Executive Committee had legal advice that leave was necessary and he could not accept the motion unless the words objected to were retained.

On a division the amendment was rejected by 13 votes to 9 and Sir Richard Thorne's motion was adopted by 16 votes to 2.

Police Fines under Medical Acts.

On the proposal of Dr. GLOVER, seconded by Mr. HORSLEY, the Council adopted the following interim report from the Committee on Fines under the Medical Acts:—

The committee have to report that they have endeavoured unsuccessfully to obtain an interview with the Commissioner of Police of the

Digitized by Google

Metropolis who suggests that the committee should communicate directly with the Secretary of State on the subject. The committee will be glad to have from the Council a direction to take this action as opportunity may offer before the meeting in May.

Direct Representation.

The next business on the programme was the following notice standing in the name of Mr. Brown:—

That, in the opinion of the Council, the time has come when it is expedient to confer on the registered medical practitioners resident in England the power of returning an additional member to the General Medical Council as provided for in the Medical Act of 1886.

On this being reached Mr. BROWN explained that in the last twenty minutes of the last day of the session he could not do justice to the subject and therefore wished for leave to withdraw the proposal in the meantime.

Leave was granted.

Unauthorised Medical Examinations.

Dr. MACALISTER called attention to memorials on the subject of illegal certificates of proficiency in departments of medicine, surgery, or midwifery received (1) from the Corporate and Medical Reform Association, Limited, and (2) from 237 registered practitioners and laymen.

Mr. BROWN, in connexion with this subject, proposed:—

That a special committee be appointed to consider and report at the next session of the Council cases of alleged infringement of the Medical Acts by persons who profess to examine candidates in medicine, surgery, or allied subjects and to grant certificates or diplomas testifying as to proficiency in any branch of medical or surgical science.

He stated that they had evidence in the memorials just referred to that there were persons who professed to examine others for proficiency with reference to diseases of the eye. This, he contended, was the thin edge of the wedge of infringement of the Medical Acts, and he thought it was indeed very desirable that any examination not authorised by the Acts of Parliament which purported to be an examination in any branch of surgery should be at once taken notice of with a view to its suppression. They had had experience in more than one case of the danger of allowing things to slide and he hoped the Council would not object to take action on these memorials in the way which he proposed.

Mr. HORSLEY seconded the motion, contending that the question involved was even more important than was represented in the memorials.

Dr. MACALISTER proposed that instead of assenting to Mr. Brown's motion the Council should refer the memorials to the Executive Committee.

After some conversation the motion of Dr. MacAlister was agreed to by a majority.

University Degrees Bill.

Dr. MACALISTER put before the Council a resolution passed by the Incorporated Medical Practitioners' Association in regard to the University Degrees Bill. The Bill, he said, was before Parliament last session and it proposed that anyone who used a degree not obtained in the United Kingdom should put after it the source of the degree. The resolution was as follows, viz.:—

The Central Council of the Incorporated Medical Practitioners' Association desires to draw the attention of the General Medical Council to the Universities Degrees Bill and trusts that no support will be given to the measure, which in the opinion of the Council of the Incorporated Medical Practitioners' Association if it becomes law will only tend to be a source of annoyance to registered medical practitioners and is quite useless to prevent the practising of quacks and medical impostors generally. It is further of opinion that if foreign graduates be compelled when using their academic letters to state the university conferring them the same duty ought to be put on English graduates, seeing that many English practitioners at the present time have their foreign degrees registered in the same way as the holders of English degrees. The council, however, is strongly of opinion that with regard to this purely honorary matter it would be better to leave matters as they are and that legislation on the matter is uncalled for.

He (Dr. MACALISTER) said that as the Council has not proposed to support the University Degrees Bill he simply proposed that they pass to the next item on the programme.

Mr. HORSLEY: I intend next session to ask the Council to support this Bill, because I think it is a most important one.

The subject dropped.

Claiming Medical Status.

Mr. BROWN moved:—

That in all cases where a person whose name is not on the Medical or Dentists' Register is charged with an offence before a public tribunal in England and Wales, and it is reported that the accused claims to be a medical practitioner or dentist, it be an instruction to the General Registrar, or in the case of Scotland and Ireland the Branch Registrars, to write to the presiding official of that tribunal stating that the accused person is not a registered medical practitioner or dentist.

The proposal was seconded by Mr. HORSLEY, but as it was objected that in its present shape it was unworkable Mr. BROWN consented to withdraw it in order to bring it up in an amended form next session.

Dental Business.

Mr. TOMES presented a report from the Dental Committee in regard to certain cases referred to it under Section 15 of the Dentists Act (1878) to ascertain the facts. There were three cases in all reported on. In the first case the committee reported that it had not been proved to the satisfaction of the committee that the practitioner did the acts complained of. In the second case it was explained that the practitioner had given up dentistry altogether and the Council resolved to take no further action. In the third case, in which the practitioner concerned was complained of for giving a certificate of death, the Council decided to adjourn the further consideration of the case until next session.

Mr. TOMES also presented a report by a special committee consisting of the members of the Dental Committee which contained the following recommendations, viz.:—

(*a*) In regard to a communication from the British Dental Association as to the issue of a notice to dentists in regard to the employment of unqualified assistants they adopted the following resolution:

That the members of the Dental Committee recommend the General Council to reissue to all persons on the Dentists Register the notice of Nov. 24th, 1892, in regard to the practice of covering unqualified persons (Minutes, vol. xxix., p. 142).

(*b*) In regard to a communication from the Dundee and District Branch of the British Medical Association as to the administration of anæsthetics by registered medical practitioners for unregistered dental practitioners, a practice which the Executive Committee has already characterised as in its opinion reprehensible, they adopted the following resolution:—

"That the members of the Dental Committee agree with the opinion expressed by the Executive Committee that the practice referred to in Dr. Buist's letter is most reprehensible, and recommend that if a charge of covering in connexion with such administration of anæsthetics were brought before the General Council it should be entertained and investigated."

In moving the adoption of recommendation (*a*) Mr. TOMES explained that the warning issued in 1892 was very similar to the covering notice issued to those on the Medical Register and said that the issue in 1892 undoubtedly did some good in the way of frightening people out of the employment of unqualified persons.

The recommendation having been seconded by Mr. CARTER was adopted by the Council.

Mr. TOMES moved the adoption of the second recommendation (*b*). He explained that the Dundee and District Branch of the British Medical Association passed a resolution to the effect that action ought to be taken in the matter of registered medical men favouring unregistered practitioners by administering anæsthetics for them. This had relation as it was worded to dentists only. He might say that he took means to inquire whether the practice was at all general and he combined with the inquiry, for his own purposes, an inquiry whether registered practitioners acted in this way for bone-setters. He received a large number of answers which proved that the practice was exceedingly prevalent in the Midlands. He obtained answers from 25 towns that medical practitioners were in the habit of giving anæsthetics for unregistered dentists. He found that in some instances the name of the registered medical practitioner was actually put up in the window of the unregistered dentist as giving anæsthetics for him. He also learned incidentally that in a few of these cases they also gave anæsthetics for bone-setters. He had got confidentially the names of twenty-three registered medical men who were in the habit, according to his informants' statements—and some of them offered to get positive evidence if it were needed—who were in the steady habit of administering anæsthetics for unregistered dental practitioners. He thought, therefore, there was very good cause for the Council adopting this recommendation. He had also talked to a number of the leading anæsthetists and he found that the Society of Anæsthetists had avoided this subject as being rather dangerous ground, but among those to whom he had spoken there was the opinion that the thing was extremely wrong and should be stigmatised and dealt with.

Dr. MACALISTER moved:—

That the reissue of the notice of Nov. 24th, 1892, be delayed until it could be accompanied by a supplementary notice to be framed by the legal adviser of the Council in the sense of the foregoing resolutions.

That was the resolution pertaining to the administration of anæsthetics.

Mr. HORSLEY, seconding the motion, said that of course

Digitized by Google

while this was sufficient as regards the dentists it was not sufficient as regards the medical practitioners.

The motion was put to the Council and adopted.

Mr. HORSLEY: Should we not have a resolution to send to the medical practitioners?

The PRESIDENT: Perhaps we had better see this draft first.

Mr. CARTER presented a report from the Executive Committee as to dental business other than matters pertaining to the Dental Committee transacted since the last session of the Council. This report dealt with four items of business. The first had reference to restorations to the Dentists Register. The second set forth a resolution of the Irish Branch Council instructing the local registrar to keep a Dentists Register and in this connexion Mr. Carter explained that the legal advisers gave the opinion that the Irish Branch Council were exceeding their powers. The third item was a letter from the Royal College of Surgeons of England saying that the recommendations of the Council in regard to dental education and examination had been referred by the Council of the College to the Board of Examiners in Dental Surgery for consideration. The last item was an application from a dentist in Ballarat, Victoria, to be registered as a colonial dentist under Section 10 of the Dentists Act on the ground that he had passed the qualifying examination of the Dental Board of Victoria in accordance with the provisions of the (Colonial) Dentists Act (1897). The Executive Committee recommended that the application be granted.

This recommendation was adopted by the Council.

Dr. MACALISTER reminded members that the granting of this application meant the opening of the Colonial list.

Close of the Session.

The PRESIDENT announced that this closed the programme of the session.

Dr. GLOVER moved a vote of thanks to Sir William Turner for his conduct in the chair. He did not remember any session when the work had been more prolonged or more trying to the President than on this occasion and he was quite sure that all the members must admire the good temper shown by him and the grasp he had taken of the business of the session.

The motion was carried by acclamation.

The PRESIDENT said he was greatly obliged to his colleagues for this vote of thanks. He admitted that the session had been prolonged and at times trying, but he would like to say this, that his colleagues had loyally supported him and he begged to thank them.

To the Editors of THE LANCET.

SIRS,—In your otherwise excellent report of the meeting of the General Medical Council on p. 1525, *re* myself you say that I was willing to withdraw my notice of motion concerning personation of registered practitioners. Permit me to point out that I did not offer to withdraw this motion and that it was subsequently carried.

I am, Sirs, yours faithfully,

Cavendish-square, W., Dec. 3rd, 1898. VICTOR HORSLEY.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND—FELLOWSHIP EXAMINATION.—The following candidates having passed the necessary examination have been admitted Fellows of the College:—

Mr. R. Allen, Belfast, M.B., B.Ch., &c., Royal University; Mr. W. J. Corrigan, Cardiff, L.R.C.P.I., L.R.C.S.I., &c.; Mr. A. Cuffe, Essex, L.R.C.S.I., L.A.H., &c.; Miss J. G. Horwood, Aylesbury, L.R.C.P. Edin., L.R.C.S. Edin., &c.; and Mr. J. O'Callaghan, Pallas-green, L.R.C.S.I., L.R.C.P. Edin., &c.

The following candidates passed the primary part of the Fellowship Examination:—

Mr. M. O'Sullivan, Dublin, M.B., B.Ch., &c., Royal University; and Mr. L. J. Whelan, L.R.C.P.I., L.R.C.S.I., &c.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.—At the monthly meeting of the President and Fellows of the College held on Dec. 2nd Mr. John Joule, L.S.A., was admitted a Licentiate in Medicine of the College.

SIR SQUIRE BANCROFT will read his arrangement of Dickens's "Christmas Carol" at St. Martin's Town Hall, Charing-cross-road, on Thursday afternoon, Jan. 12th, 1899, on behalf of the Royal London Ophthalmic Hospital, Moorfields.

SANITATION AND RELIGION.—At the Plympton (Devon) Ruridecanal Conference, held on Dec. 1st, Mr. S. Noy Scott, L.R.C.P. Lond., read a paper on Sanitation and Religion in which he contended that the promotion of santation was distinctly a religious duty.

MEDICAL MISSIONS.—At a large meeting held in Plymouth on Nov. 30th the Bishop of Crediton and Dr. Lankester, medical secretary of the Church Missionary Society, strongly advocated the claims of the proposed medical mission for the Khartoum and Nile Valley.

LITERARY INTELLIGENCE.—Mr. Henry Frowde, Oxford University Press, is publishing a monograph on the Micro-organism of Faulty Rum, by Professor V. H. Veley, F.R.S., and Lilian J. Veley. We are informed that the micro-organism has hitherto escaped observation because it was supposed that no organism whatever could live in liquid of such alcoholic strength as rum.

THE GENERAL MEDICAL COUNCIL AND UNQUALIFIED ASSISTANTS.—At Landore (Glamorganshire) station on Nov. 28th a deputation met Dr. J. Havard Jones on his return from London, where he had appeared before the General Medical Council on a charge of employing an unqualified assistant, the case being dismissed. A brass band and about 4000 colliers, &c., escorted Dr. Jones to his residence. The whole village was illuminated.

NEW HOSPITAL AT NEWTON ABBOT.—A new hospital given to Newton Abbot, Devon, by the late Mrs. Fisher in memory of her late husband and built on a site of land presented by Mr. Scratton was formally opened by Mrs. Scratton on Nov. 29th. The building will contain accommodation for 27 in-patients and has been erected at a cost of £6000. The residents of Newton Abbot subscribed £1044 in commemoration of the Queen's Diamond Jubilee and this will be used towards the endowment of the hospital. A glass air-tight instrument case has been placed in the operation theatre by Mrs. H. S. Gaye in memory of her late husband, Dr. Gaye, who was the founder of the old Newton Abbot Cottage Hospital.

UNIVERSITY OF CAMBRIDGE.—The following elections of medical graduates as members of boards and syndicates are announced:—Dr. D. MacAlister to the Agricultural Syndicate and the Medical Board; Dr. F. Darwin to the Museums and Lecture-room Syndicate; Dr. Guillemard to the Antiquarian Committee; Dr. Laurence Humphry and Dr. Collingridge to the State Medicine Syndicate; Dr. Barclay-Smith to the Biology and Geology Board; Mr. E. G. Browne to the Board for Indian Civil Service Studies; Dr. Bayley Balfour to the Board of Electors for the Chair of Botany. The examiners in sanitary science for the ensuing year are Dr. Anningson, Professor Kanthack, Dr. Collingridge, Dr. Lane Notter, and Dr. John Stevenson. Mr. Stabb, university lecturer in midwifery, is appointed to examine in the third M.B. examination instead of Dr. Barbour who is indisposed. The John Walker Studentship for Pathological Research, value £200 a year for three years, will be vacant this month. Candidates are requested to communicate with Professor Kanthack before Jan. 19th, 1899.

CORPORATE AND MEDICAL REFORM ASSOCIATION, LIMITED.—At a meeting of the Executive Committee of this association, held at the residence of Dr. Tom R. Taylor, Guilford-street, Russell-square, W.C., on Dec. 6th, Mr. A. S. Morton in the chair, after election of eight members resident in Oldham, Leeds, Croydon, and Gravesend, on the secretarial report of proceedings on the memorial presented by the association to the General Medical Council, a resolution was unanimously adopted thanking Sir Christopher Nixon, Sir William Thomson, Dr. Glover, Mr. George Brown, Mr. Victor Horsley, Dr. William Bruce, Dr. Bennett, and Mr. Tichborne for proposing, seconding, and supporting a motion "That a special committee be appointed to consider and report at the next session of the

Digitized by Google

Council all cases of alleged infringement of the Medical Acts by persons who profess to examine candidates in medicine, surgery, or allied subjects, and to grant certificates or diplomas testifying as to the proficiency of any branch of medical or surgical science."

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on the afternoon of Dec. 5th, Sir James Crichton Browne, M.D. Edin., F.R.S., treasurer and vice-president, presiding. Among others Dr. C. T. Williams and Mr. H. W. Allingham were elected members. The special thanks of the members were returned to Dr. George Wyld for his present of a portrait of Dr. Thomas Garnett, first professor in the Royal Institution.

THE PLAGUE COMMISSION.—According to the *Times of India* the Governor-General of India has published a resolution with reference to the Plague Commission that "there must be many valuable items of information to be ascertained from officers who have been employed on plague operations that have not been recorded in official reports, and there are also many circumstances connected with outbreaks in different places which require to be locally examined by persons who can collate facts and form conclusions which will be accepted by the public as well as scientific opinion in respect of them." The resolution adds that the Government of India "regard it as very desirable that authoritative scientific opinion be obtained as to the value of prophylactic and therapeutic serums in dealing with the plague."

LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration of Surgical Cases. (Post-Graduate Class.)

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE CONSUMPTION OF ALCOHOL IN FRANCE.

IN 1874, according to *La Tribune Médicale*, the number of drinking establishments in France was 342,980 without counting Paris, the capital being responsible for about 40,000. Since then, although the population has remained comparatively stationary, the liquor shops have increased to an alarming extent, the total number in 1896 amounting to 432,047, which represents an augmentation of 25 per cent. With respect to the quantity of wine consumed by individuals Boulogne-sur-Seine heads the list with the enormous allowance of 58½ gallons per head. Next in order come Nice, Saint-Etienne, Grenoble, Troyes, Toulouse, and finally Paris, where the annual amount per head is 44·6 gallons. As regards alcohol in the form of brandy and other spirituous compounds Rouen stands first with nearly 4 gallons per head per annum. Havre and Cherbourg are not far behind, and the next in succession are Boulogne-sur-Mer, Brest, and Lorient, all being seaports. In Paris the individual consumption of alcohol is about 2 gallons each year. Considering that women and children are included in the statistics and that male abstainers exist these amounts can only be styled excessive.

"THE QUALIFICATION OF L.A.H. DUBLIN."

To the Editors of THE LANCET

SIRS,—Under the above heading in THE LANCET of Dec. 3rd, 1898, it is stated: "The Licence of the Apothecaries' Hall of Dublin in 1880 was, as it is now, a Licence in Medicine only." I have to inform you that the diploma of this Hall now entitles the holder to be registered in medicine, surgery, and midwifery, as well as to act as a pharmacist for compounding prescriptions. Your kindly correcting the error will greatly oblige the Governor and Court.

I am, Sirs, faithfully yours,

ROBERT MONTGOMERY, M.R.C.S. Eng.,
Mary-street, Dublin, Dec. 5th, 1898. Secretary.

*** Our statement was based upon information obtained for us from the representative of the Apothecaries' Hall of Dublin upon the General Medical Council.—ED. L.

BAD STEAKS.

THE case of Frost *v.* North heard a short time ago in the Shoreditch County Court in which His Honour Judge French has since refused to give leave to appeal is one apparently of considerable hardship to the plaintiff. An omnibus-driver entered an eating-house where he was accustomed to dine and ordered a beefsteak, poured some sauce over it, and proceeded to eat it. The first mouthful struck him as tasting unpleasantly; thinking the sauce was bad he scraped it off, and having eaten one or two more mouthfuls declared the meat bad, ate no more, and went out. He subsequently suffered more or less severely from ptomaine poisoning and in consequence sought to recover damages from the person who sold him the steak. In these circumstances one might have thought that if the plaintiff was to be defeated it would be owing to some principle of law whic

Digitized by Google

absolved the eating-house keeper from the necessity of supplying wholesome food to his customers. The ground, however, of Judge French's decision in the defendant's favour was, to quote his words as reported in giving his final decision, "If a man is such a fool as to eat bad steak then he must take the consequences." One can only wonder on what evidence such a decision was based, as legal decisions are usually supposed to be based on sworn testimony which in this case would have been that of an expert witness. No one surely can have informed the court that in cases of unwholesome food the taste is so convincingly obvious that no one but a fool would eat or drink it. If this were the case typhoid fever and various other diseases would be confined to persons of defective mental capacity. We should have thought no one would blame an omnibus-driver for not knowing that two or three mouthfuls of high meat might make him ill. He ate no more, apparently, than enough to satisfy himself that the food was nasty, but the learned judge seems to have arrived at the conclusion that it was so nasty that it ought to have warned him before he ate so much. How his honour could come to so decided an opinion as to the precise pitch of nastiness to which the steak had attained is the most puzzling point of all. The degree of nastiness could hardly be established by evidence.

THE MEDICAL PROFESSION AND SECRET REMEDIES.

To the Editors of THE LANCET.

SIRS,—Will you be so good as to give me your opinion on the following. Can a member of the profession dispense a secret remedy (the composition of which is known only to himself) and with which his name is associated more or less) without laying himself open to a charge of "unprofessional conduct"?—I am, Sirs, yours faithfully,

Dec. 5th, 1898. M.B.

*** A member of the medical profession should under no circumstances dispense a secret remedy.—Ed. L.

QUACKERY.

UNDER the heading "A Herbalist in Trouble" we noted in THE LANCET of August 27th the fact that Mr. Samuel Matthews, a former member of the Norwich Town Council, had been fined £1 for illegally using the title of "Surgeon" and £20 at the suit of the Society of Apothecaries of London for illegally acting as an apothecary. From a cutting from a Lowestoft paper of recent date we see that "Dr." Matthews and his son still carry on their trade of quackery. We do not know whether they are still acting as "apothecaries"—that is to say, in the sense in which they would come under the arm of the law—but, as we have so often said, if it be necessary to have a licence to sell buttons and string in the street or from door to door we cannot understand why it should not equally be necessary to have a licence to be a quack practitioner.

"THE TITLE OF 'DR.'"

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 3rd Mr. Collingwood considers it harsh that non-graduate diplomates should not be permitted to use the title of "Dr." Did it ever strike your correspondent that the harshness is on the other side? I held the two diplomas (not the double but by separate examinations) of Edinburgh and after being in practice a considerable number of years went to much trouble and expense in reading for the degree at St. Andrews. During the spare time of about two years I denied myself the recreation that my daily work justified me in taking for pleasure and rest in reading for the examination and, I may observe, had I not done this I should have returned, as one gentleman did in my year, without the degree. The examination was a thoroughly searching one and covered pretty well the whole field of medicine and surgery, notwithstanding the notion which appears to exist in the minds of some who have never crossed the border in their lives that the ten degrees granted each year are given away. Twelve candidates were summoned and if less than ten were found to satisfy the examiners others were telegraphed for from the reserve list of candidates in waiting each year. I had to wait three years. I therefore fail to see the harshness meted out to diplomates who as students knew perfectly well that if they expected the title of "Dr." they must take two (only) of their years at a university and that if they went for the College diplomas only they would remain only "Misters." I for one knew this, and though I could not afford it as a student I determined at the first opportunity to obtain a university degree. St. Andrews now only grants the degree by graduation, but Durham is still available to qualified men over a certain age and Brussels is always available. I am, Sirs, yours faithfully,

Dec. 4th, 1898. M.D. ST. ANDREWS.

THE CHORLTON GUARDIANS AND LADY MEDICAL OFFICERS.

QUITE a warm discussion took place at the meeting of the Chorlton Board of Guardians on Nov. 24th *re* lady medical officers showing that even yet their advent does not always herald peace. One of the guardians objected to a minute in the report of the house committee "recommending the appointment of a lady doctor temporarily to fill the place of Dr. Higginson" who was not well at the time. It seems that there was a difficulty in obtaining the services of the creature called by a lady guardian a "man-doctor" for so short a period as eleven days. One lady medical officer is at the workhouse already, but the work is heavy and no doubt help was required, but some of the guardians objected to a friend of the lady resident medical officer being appointed and one "could not understand why there should be all this wire-pulling to get women doctors where they were not wanted—at any rate by the workhouse people. If it were intended to fill the institution with women doctors it would be as well for them to know at once." It is curious and no doubt speaks well for the chivalry of some of the "man-doctors" that the chief defence of the action of the house committee was by a (male) medical guardian. One of the lay guardians drew a melancholy picture of the condition of the profession when he stated that "there were scores of medical men in the neighbourhood unemployed"—let us hope he is mistaken—"and yet the board had to telegraph to London in order to get a woman to look after the workhouse! It was a disgrace to ask women to undertake such a work." There is no question that in the poor districts of our large towns there is frequently overcrowding of young medical men who hope to rise on the professional ladder by beginning at the lowest rungs, and it is difficult to imagine that the house committee sought very diligently for a temporary substitute for Dr. Higginson among the local men before recommending the appointment of another lady medical officer from London.

"OYSTERS."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Woodward's query in THE LANCET of Dec. 3rd, allow me to say that at Helford, Cornwall, natives may be obtained absolutely free from contamination of drainage, there being no town up the estuary. I am, Sirs, yours faithfully,

East Molesey, Dec. 3rd, 1898.] W. W. HARDWICKE, M.D. St. And.

"FIST, KNIFE, AND REVOLVER."

MR. FRED GALE, writing in the *Globe* under this heading, gives vent to an aspiration the ferocity of which is justifiable, nay laudable. "Let us hope," he writes, "that we may hear yet of a knife or revolver ruffian being torn to pieces by the populace." Mr. Gale believes that fifty years ago, if times were rougher they were in some respects more humanly minded, and he is certain that any man in a street row who had kicked his enemy or drawn knife or revolver upon him would have been lynched. Now such actions by Hooligans seem in accord with the feelings of the mob.

IMPROPER ADVERTISING.

A CORRESPONDENT sends us a card which he assures us is being distributed by post to "nearly everyone whose name is in the local directory." We append the wording on one side of the card; on the other is a statement to the effect that the card entitles the holder to one week's medical attendance with medicine at home or at surgery according to fee paid.

THE

FULHAM DISPENSARY & SURGERY,

(Established 1886.)

FOR

GENERAL AND SPECIAL DISEASES,

794, FULHAM ROAD, S.W.

CORNER OF FULHAM PALACE ROAD.

ADDITIONAL HOURS OF ATTENDANCE.

Morning 10 to 12. Afternoon 3 to 4. Evening 7 to 9.

Sunday, 7 to 9 Evening.

Advice and Medicine, etc., (Surgery) ... 1/-

Attendance & Medicine, (At Home) ... 2/-

Midwifery, &c.

The one saving clause in the transaction is that there is no name of a practitioner on the card. If the practitioner who distributes these is qualified he must know that he is not acting in accordance with the recognised canons of professional behaviour. Of course he may be unqualified, in which case the Apothecaries' Society of London might look into the matter.

MEDICAL PRACTITIONERS AND CHARITY MIDWIVES.

To the Editors of THE LANCET.

SIRS,—Without reference to any particular institution by name I would like the opinions of readers of THE LANCET on the following point—viz., how is it that numerous maternity charities are able to carry out their work in the face of the existing resolution of the General Medical Council with regard to the employment of unqualified persons as assistants or otherwise without rendering the medical staffs of these places liable to be judged as guilty of infamous conduct in a professional respect?

Without travelling beyond the town where I reside and which also shall be unmentioned the following existence of affairs here has raised the question in my mind. The local lying-in hospital has at varying distances of from half a mile to a mile or more several establishments. All these are each manned, if I may use the word, by one or more midwives with probationers. The parent institute has, in addition, a resident qualified and registered house surgeon and a visiting medical staff. I should mention, perhaps, that the branches

Digitized by Google

are only accommodation residences for the midwives to dwell at for the convenience of the poor of the district who are attended at their homes by the former. From the parent institute midwives also go out to attend labour cases in the same way as the midwives from the branches do. The work of these establishments is carried out as follows. When a call comes a midwife, accompanied generally by a probationer, goes out to the case. They carry through the confinement, and unless something abnormal arises neither the house surgeon nor any one of the visiting staff is summoned. True, the house surgeon is expected to see the patient once during the lying-in period if she goes on all right; only if wrong does he give any further attendance. The midwife during the all-right term attends and treats the patient until well without any supervision except that which I have mentioned as fulfilled by the house surgeon. Taking these facts as they stand I would inquire whether the employment of midwives as here depicted, where the immediate personal supervision of a registered medical practitioner is dispensed with, is legitimate or not? In my opinion it is illegal, but rather than depend on my own judgment I wish to learn from others if they think the registered medical practitioners who are privy to and sanction the substitution of their services to unqualified persons and who knowingly countenance, assist, and coöperate in the employment of unqualified persons to attend and "treat patients in respect of matters requiring professional discretion and skill" in the manner I have pointed out are, or are not, guilty of "covering" or of employing unqualified assistants, or are in any way liable to censure by the General Medical Council?

I am, Sirs, yours faithfully,

Nov. 29th, 1898. MEDICAL PRACTITIONER.

"THE COLOUR OF NEWLY-BORN NEGRO CHILDREN."

To the Editors of THE LANCET.

SIRS,—Since for some reason or other there appears to be a divergence of opinion as to the colour of newly-born negro children an exceedingly limited experience of my own may serve to throw a ray of light upon what at present seems an open question. Several years ago when attending midwifery for the charity of the London Hospital I attended a fair, buxom Englishwoman and to my astonishment at the time I found a strong and healthy baby upon the bed which was in every way perfect but looking as if just out of walnut pickle. Upon interrogating the mother she informed me that her husband was a man of colour and also that I probably might know him, as he was a vendor of "the perfumes of Araby" and India which he sold about the East-end of London. I was then able to call the husband to my memory and well remembered him as a man of similar colour to the baby although he was not a negro. Now if a walnut-coloured baby can be born having a walnut-coloured father and a fair-coloured English mother, I think it fair to assume that a baby born whose parents are both negroes will in all probability be even darker than the walnut baby it was my good fortune to bring into the world.

I am, Sirs, yours faithfully,

London, S.W., Nov. 29th, 1898. ALBERT S. MORTON, M.D.

To the Editors of THE LANCET.

SIRS,—I see from an annotation in THE LANCET of Nov. 26th that there is some difference of opinion on the colour of newly-born children of African parentage and this is not very surprising to those who have any extensive experience in the matter. The fact is they are not, like Joseph's coat, of many colours, but of many shades of one colour. They are not white and they are not pink. You have often seen a newly cleaned calf's head in a window in the Strand. This is about the ground colour, but I have never seen them as white as this; rather this colour with a light splash of black ink on it. Or if you can imagine a new chamois leather in the hands of a groom which has almost all its yellow colour washed out and which has been once or twice washed in dirty water; this is the lightest shade. The colours may be from this to the colour of the same chamois leather after a month's constant use, the darker shades of grey hiding the yellow. The grey being dark the other dark parts of the body referred to in your article are a degree darker to a dark *black*; not blue and not lead colour. This is the condition I have seen in healthy, strong children. Where the child is unhealthy, where there is not good action of the lungs, and where there is some admixture of white blood this colour has always added to it various shades of black magenta or a black red. I have attended the same woman many times and the infants have never been of the same shade. This is my experience of sixteen years on the north coast of South America.

I am, Sirs, yours faithfully,

Nov. 28th, 1898. GUIANA.

*** We fancy that the various shades of pigmentation in the young of animals which when adult are black or almost black are to be found throughout the animal kingdom and are not confined to human beings. Take, for instance, the hippopotamus which when full grown is of a very dark mahogany colour or almost black. Its young when newly born is of a greyish pink colour. According to Buckland, Mr. Petherick, the African explorer, captured a young hippopotamus about two days old near Khartoum. He was brought to England, being on his arrival there about eight weeks old. Not having been able to have a bath on the way home his skin was like the bark of an old tree, but after a course of warm baths in the Zoological Gardens "his skin soon began to get soft, slimy, and of a black pinkish colour" ("Curiosities of Natural History," Third Series).—ED. L.

RIVAL QUACKS.

IN the Queen's Bench Division on Dec. 2nd there was heard, before Mr. Justice Wills and a special jury, an action brought by Henry Doveton, a quack medicine vendor, against other quacks known as Dr. Williams of Pink Pills notoriety. The action was for false imprisonment and malicious prosecution. Doveton, it appears, had been charged by the defendants with selling pills as Dr. Williams's Pink Pills which were really his own. At Lincoln Assizes the grand jury ignored the bill as no witnesses appeared for the prosecution. Counsel for the defendants in the present trial said that this was owing to a mistake on the part of the witnesses as to when the trial came on, and the judge who had presided at these assizes was now unkind enough to say that he had thought at the time that the whole thing was an advertisement. Plaintiff, in giving evidence, said that he never said that his pills were those of Dr. Williams. As a matter of fact he carefully explained that they were not, but were much better. Mr. Justice Wills gave judgment against the plaintiff. So possibly, according to the old saw, honest men will come by their own.

MESSRS. ADAMS AND PARKES, medical accountants, &c., 8, John-street, Adelphi, have sent us a specimen of a pocket celluloid almanac which forms also a useful memorandum tablet. It is enclosed in a paper case stamped in imitation of crocodile skin.

E. C. will find references to the subject in our columns. The companies cannot be the willing agents of the homicidal parents, for it would not pay the companies if the majority of the infants insured with them died. Our correspondent is, we think, a little carried away by the tragedy of the subject.

M.D. Dunelm.—The Royal College of Surgeons of England might take notice of the matter in the first medical man's case if the publication is brought to their attention. The second author obtained his degree from Edinburgh and the university might be communicated with.

R. L. B.—The analysis does not present any unsatisfactory features, but under the circumstances mentioned it is desirable that further examination should be made at intervals so that periodical liability to contamination may be discovered or variation in composition detected.

Mr. Joseph Ward will find complete information concerning the regulations of both departments in the current Medical Directory, page 1843.

Mr. William Dalton.—We do not know any financiers and do not appreciate the merits of the invention from the description forwarded to us.

L.M. should write to the chief constable of the county, giving evidence and substantiating the accusation of favouritism.

X. (Birmingham).—We do not know the book to which our correspondent refers.

The Harveian Lectures

ON

DISEASE, ITS TREATMENT AND THE PROFESSION OF MEDICINE IN 1899.

Delivered before the Harveian Society on Dec. 1st, 8th, and 15th, 1898,

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND JOINT LECTURER ON MEDICINE TO THE MEDICAL SCHOOL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

LECTURE I.

Delivered on Dec. 1st.

THE PRESENT ASPECTS OF DISEASE.

GENTLEMEN,—In addressing you to-day at the bidding of the President and Council I feel that the responsibility of the choice is theirs, not mine, and I need say little of my inadequacy to an honour which is alike difficult to accept, to refuse, or worthily to fulfil. Disease, treatment, and the profession of medicine are topics vast and varied yet capable of being brought into harmony; but in connexion with them your attention will be invited only for those changes which are special to our times. The more I have thought the closer has seemed to me to be the mutual influence at work between the circumstances of the medical profession and those of disease and of treatment. Their joint consideration might perhaps lead to a better understanding of some of our medical anomalies. It would be difficult to find facts possessing any novelty for a learned audience such as this. But in opinions there is endless variety and in variety there may be an escape from tedium. Controversial questions will be avoided; but from delicate questions there is no escape; and I may best conform to your wish by giving you my own opinions without reservation in the welcome expectation of your criticisms at some early date.

THE NINETEENTH CENTURY AND THE "FIN DE SIÈCLE."

From the year 1899 we shall soon be looking back upon the greatest century medicine has ever known, a century of labour and of results. But our recent vicissitudes, our changes, and our prospects will be sufficiently illustrated by a review of a shorter period, that which is included within the memory of our own generation. It may be asked whether there is anything special in this date to justify a retrospect. "Eadem sunt omnia semper." Dates have for us their significance and in this case the significance lies partly in the expectancy with which the centennial turning-point is looked for by us all. But there is also in our contemporary conditions a special intrinsic excuse for retrospection. Never probably was the future questioned more keenly as to its probable event, for, great as are the wonders we have watched, greater wonders are in reserve. It may be said of this as well as of the last century, that the end seems to be the most exciting part. In the closing days of that century the *dramatis personæ* of medicine were the great physician with his gold-headed cane, the surgeon, great, but of inferior grade to that august person, and the humble apothecary, who would not have ventured to sit down in the presence of these great beings. Gradually, as time went on, the class distinctions became less marked, and now, in the closing years of this century, the physician has lost his cane and his pomp and is only distinguished from his fellow workers in more general subjects in that he is credited with a more ample knowledge of the matters to which he restricts his attention, while the humble apothecary of the early days of the century, who was not paid for his professional advice, but solely for the medicines which he supplied, has given place to the highly accomplished practitioner of medicine and of surgery. He is to be found everywhere through the land, well taught, with a great knowledge of his profession, careful and judicial, wanting but little outside assistance in his work and then only to help to solve some of the difficult or insolvable problems which present themselves in the practice of the profession.

"Fin de siècle" is not an idle term. The whole world is conscious of changes, profound and rapid, and to these none are more keenly alive than ourselves who stand by and watch. They may not have been so stormy as those of a hundred years ago, yet radical, and some of them in a quiet way even subversive. Satirists have described our "fin de siècle" degeneracies. Fortunately degeneracies, like disease itself, which ever renascent life ultimately wears out, are mere passing evils. In the long run change makes for good. Moreover, all the changes have not been revolutionary. There have been evolutionary changes as well. Were I asked to name those of our changes which are most momentous my answer would be—the control of disease and the emancipation of women; the one affecting the entire human race, the other one half of mankind directly and indirectly also the other half. Their influence is already manifest, but they are fraught with expanding results.

One aspect of the emancipation of women belongs strictly to hygiene and under the heading of "physical education" will be dealt with later. The wide subject of their participation in the work of the world since weaving and spinning, once laborious and useful avocations, have been abandoned may detain us for a few minutes. But between the disappearance of the spinning-wheel and the opening up of higher work for women there is a mysterious interruption in the record of their occupation and one begins to wonder what became of the energy which for that interval of years is imperfectly accounted for and how so little mischief to health seems to have arisen from it. A great change has now set in. Higher education is extended even to the lower middle class and, through the Board schools, to the lower class itself. The natural aptitude and pliability of the sex are thus given their opportunity and this has been seized with eagerness. The secret of the wealth of France is that nearly every man and woman contributes to production. Until recent years in this country a large section of our female population had been unemployed; much may therefore be expected from the mobilisation of so great a reserve. Quiet and peaceful studies for the gentler sex; the forum, with its struggles and excitement, for man. This division of labour would apply, with modifications, throughout the scale of professions and employments. In all sciences if their labours are to be divided, and particularly in botany and biology, the domain of fine and patient observations seems to be specially indicated for women. In literature there is in the place of the aimless reading of novels a tempting field now vacant, since in our profession and in others also philology has been discouraged on the plea of over-pressure and one of the richest and most useful of our educational studies is therefore neglected. Molière ridiculed the ladies who took an interest in the study of Greek, but we should now hail their assistance whilst envying their opportunities of combining one of the highest personal pleasures with public advantage.

The accession of women to the ranks of the profession is for us the most important part of this large question. A need has been supplied and a vacancy filled in lines of work for which neither aptitude nor opportunity fit the medical man. A providential coincidence may be traced in this development at a time when the responsibilities of civilising new worlds are, as it were, suddenly cast upon us. Civilisation in its commercial aspect is now carried on at racing speed by steam and electricity. True civilisation of the human beings themselves could be carried out with like rapidity only by the influence and example of women, and who among them can compare in influence and general fitness with the members of our profession under whose enlightened guidance other workers might carry out the beneficent scheme? How different this scheme of civilisation from the former methods which relied upon ardent spirits and the rifle as their chief weapons. India, China, and Africa are the vast fields which will be open to this, the highest of civilising agencies next to that of the missionaries whose labours it would assist. But the number of those fitted and willing to embark upon such arduous enterprises must remain limited. Within our own boundaries, however, plenty of scope may be found for a majority of the workers. The same civilising influence has to be carried into the heart of our cities and into the homes of the people. The enormous wealth of this country is in strong contrast with our pauperism which a long period of State relief has failed to remedy. It is becoming more and more evident that individualism in charity is the only hope for a cure and that the best way to raise the level and provide for the comfort of the lower classes is the

Digitized by Google

education of the women by women. This is the kind of work which would throw usefulness and interest into thousands of lives imperfectly satisfied by the mere vanities of the hour and could achieve, if organised, incalculable good.

THE CONTRACTION OF THE FIELD OF MEDICAL PRACTICE.

The other great fact around which my remarks will centre is the increasing limitation of disease and the contraction of the field of medical practice. It will be seen that in many cases ailments which hitherto had belonged to the exclusive care of the general practitioner have had a tendency to escape from his undivided control. The causes of this change are various, its ultimate consequences of considerable importance, and to them some attention will be devoted in due course. Other changes no less remarkable have occurred affecting the status, the practice, and the prospects of the profession. They have taken place at the two extremes of the professional ladder and it is significant of the completeness of our representative character of the entire human family that these changes should have been in opposite directions. The same period which has witnessed the undue influence of democratic ruling on some of our members has also thrown lustre upon the entire body by the conferment upon one of us of the highest honour in the state. Changes in the latter direction belong to those which I have termed "evolutionary." The other change we must regard as a "revolutionary" one and therefore subject to revision. It is one which might be regarded as not concerning us, yet there is good ground for our discussing it. Whilst the difficulties of some of our *confrères* have been at their worst, what notice have we taken of them, you and I? Neither the consultant nor the affluent general practitioner has any personal share in these troubles. Nevertheless, they affect the vital interests of the profession by affecting individually its members, those least likely to have the necessary opportunities and power for grappling with the question. Is it not part of our duty at least to take cognisance of their troubles, and when these are realised to help them to find a remedy?

THE GRADUAL DIMINUTION IN THE PREVALENCE OF DISEASE AND ITS CAUSES.

The prevalence of disease has considerably diminished within the memory of the present generation and if its characters have altered in any degree the change has been rather in the direction of attenuation. The origin of this improvement is not far to seek; it is to be found in our improved knowledge of the causes and of the natural history of disease and in the system of repression based upon it, which includes direct methods applicable to some of the infectious diseases and indirect methods for other forms of disease. These two groups will claim our separate consideration.

The parasitic nature of infective disease.—The notion of the parasitic origin of disease dates back to a remote antiquity, but the full proof of its correctness has been delayed until our own times and with it the idea that their spread can be controlled and even arrested. Contagion was a powerful argument for the theory of a living and continuously multiplying *ens morbi*. But where, as in the endemic diseases, a direct transmission failed to be traced the elements were made to bear the blame. The mysterious cropping up of epidemics led support to the theory of spontaneous generation, and, strange to say, even within our own time, spontaneous generation was for a while the burning question until all doubts were finally set at rest by Pasteur. We are now aware that whatever may be the individual channel of communication the cause of each of the infective diseases is a living thing, capable of being destroyed in its nidus, if only we knew how, and of being stopped in its transit.

This result due to modern science and research.—The progressive diminution in the prevalence of some of our most fatal diseases is not merely fortuitous but the direct result of our successful interference. Each of the great victories over disease has been the reward of a long and systematic siege planned in each detail by scientific knowledge. This plan of campaign is in some respects analogous to that of the astronomer in quest of a missing planet. His early calculations seem to have no reference to the object which he seeks, but with fatal precision they ultimately guide the axis of the telescope. It is not for me to depreciate the value of imagination. We owe much to it in science, for without its help some of the most fruitful facts might remain unproductive. This is, indeed, the history of many of our greatest discoveries. They have been rediscovered long after the premature spark of genius had flashed in vain for a world too obtuse and unimaginative.

Specialism in research; bacteriology.—Progress nowadays is subservient to the trained use of instruments of precision and to the faultless accuracy of scientific experiment. Specialism has been much decried. It is a necessary evil of the day, or rather it is the first essential for good work. Nowhere is this more apparent than in the progress of pathology. Without bacteriology, that most specialised of all our branches of study, none of our latest discoveries could have been made and it is through the concentration of labour upon special lines that its greatest results have been attained. All honour is due to Koch who opened up the road to trustworthy experimentation by his careful elaboration of the technique and his broad generalisations on the principles of bacteriology as a science to be placed within the reach of the ordinary pathologist and within the capabilities of a properly-equipped laboratory. It would be a pleasant task to dwell upon the now extensive list of those diseases which have been traced back to their real causes. Relapsing fever, tuberculosis, leprosy, diphtheria, cholera, tetanus, malaria, actinomycosis, glanders, dysentery, typhoid fever, pyogenic infections, and the plague are no longer mysteries, and they by no means complete the list. Each one of these discoveries has cost the long and assiduous labour of men who had had a complete training in each of the ancillary sciences before starting upon their special investigation. It has been our privilege to live within the day of Pasteur, Lister, Virchow, Cohnheim, Koch, and many others to whom humanity is immediately indebted for our present immunities and to whom was first given the power to make and to unmake disease. We cannot forget, however, that the foundation was laid long ago by such men as John Hunter, Jenner, Baillie, Laennec, Cruveilhier, and Rokitansky; and to these immortal names others too numerous to bring up form an honourable escort.

Diagnosis more scientific.—Etiology loses its use unless disease be recognised. In diagnosis also the most brilliant advances have been worked out in the laboratory. Bacteriology has given us tests for some of the most virulent affections and the other sciences have been drawn into the service of the physician. Diagnosis must always be an art, but it is becoming more and more a science, needing technical knowledge and skill and an increasing supply of instruments of precision. One of our most striking innovations is the employment of scientific aid by the practitioner and the adequate means which have come into existence to supply his requirements. At hospitals all this is provided by the clinical laboratory which is therefore an essential part of their equipment irrespective of any educational object.

The suppression of disease.—It is to Jenner we owe the great idea that a disease may be practically stamped out by a thorough application of some universal protection. I need not weary you with figures, but you are aware that wheresoever efficient vaccination and revaccination are performed the mortality from small-pox is almost *nil* and its incidence is restricted both in numbers and degree. In our own country it survives only by the will of the people. The reduction in the prevalence of the fatal zymotics can be traced to the study of the germs of disease and ultimately to that biological study of the ferments which led the genius of Pasteur to his vast inductions. Preventive inoculation has been practised for cholera, plague, enteric fever, and diphtheria; these diseases, however, are not so prevalent as to warrant universal prophylactic treatment. Vaccination still stands alone as a universally applicable prophylactic and it stands almost exactly where Jenner left it with the single additional improvement of asepsis. It is also to these guiding studies that we owe those immense practical realisations of Lister which have made surgery and which have influenced medicine to its foundation, and it is to them that we are indebted for the fertile teachings of Parkes on hygiene.

The share of hygiene in the prevention of disease.—To hygiene, inspired of bacteriology, are due most of our practical measures of prevention. The suppression of cholera, of relapsing fever, and of typhus fever, the limitation in the spread of the common exanthems, the successful though still fractional results in the limitation of phthisis, and, not least, the improved health and strength of the rising generation,—all this has been the direct fruit of a faithful application of its principles and these results must raise the

Digitized by Google

subject of public health to the highest place in the service of the State and in the opinion of the profession. The methods of cure and of prophylaxis are of two kinds—direct and indirect. Bacteriology which has done so much in the etiology of disease has also in some instances provided us with its direct cure. But in the line of prevention we have chiefly utilised the indirect methods of hygiene. Hygiene is likewise, in a modified sense, a curative agent, for when associated with medication it lies at the root of some of our methods of cure, as in the case of malaria and syphilis. Again, we are indebted to it for the suppression of the epidemics of puerperal fever and septic peritonitis. This great progress was initiated by Semmelweiss, but the modern life-saving reforms did not become part of practical gynæcology until Lister's great work had shown how the previously unchecked spread of septic infection could be absolutely prevented.

Pyæmia and septicæmia which claimed so many victims are now almost unheard of. Moreover, suppuration itself, with its long delays, its risks and sequelæ, has now ceased to be regarded as part of the process of healing. This simplification in the tale of surgical sufferings is not limited to the traumatic group. I need merely mention abdominal surgery and the rapid relief which it often affords to chronic affections of the stomach, of the bowel, of the kidney, of the liver, and of the ovary.

The share of bacteriology in the cure and prevention of disease.—Bacteriology has in some diseases supplied us both with the prevention and the cure. But in this country the preventive methods have not had the opportunity which unfortunately obtains in the East. The treatment of diphtheria is the most brilliant example of the curative value of the serum of immune animals in which we must admit the existence of some principle, biological or chemical, endowed with the power of neutralising the toxins generated by the bacillus; the immune serum, although it is itself unable to check the growth of the bacillus, still leads in some mysterious way, perhaps by setting free the full contingent of phagocytes previously paralysed by the toxins, to the arrest of that growth. Less successful but not wanting in promise are other forms of serum treatment. The streptococcus serum, the pneumococcus serum, the antitubercle serum, and the antitoxin treatment for tetanus and for plague are instances in point. Within quite recent years the immunisation of those likely to be exposed abroad to the infection of such virulent diseases as cholera, plague, and typhoid fever has been systematically practised; but since diphtheria has become amenable to treatment in this country there is less necessity for any protection of this kind.

The respective share of medicine and surgery in the repression of disease.—The contemporary advances of surgery have been the evolution of an art which had previously desired its opportunity now given to surgeons by anæsthesia and antisepsis. As the opportunity was afforded a new surgery grew up under their hands, characterised by skilful manipulation and by infinite ingenuity of device. A tribute is also due to dental surgery, the improved methods of which are of incalculable service in the rational treatment of some lingering ailments. The prime honour in these surgical triumphs is, however, due to that science which elaborated antisepsis, the science which led Jenner to his great results, which subsequently guided Pasteur and, as a crowning benefaction to humanity, inspired Lister and his work. The principles of antisepsis have been worked out on those lines of research which are identical with the laboratory methods carried on in the service of medical questions. In all that preliminary research and experimentation there was very little of surgery in a strict sense, but a great deal of biology and chemistry.

Medicine vindicated.—Whilst the brilliant record of surgery has tended to eclipse everything else the achievements of medicine have been unnoticed or minimised. To place things in their true light the province of surgery would seem to be essentially curative. It may save life or limb, but this is a gain to the individual only. Medicine has done more in prevention. Its dealings with the individual are not always brilliant and its attempts at the cure of disease are too often absolute failures; but it has succeeded in protecting not the individual alone but the community against decimating diseases. The suppression of a single disease, such as typhus fever, small-pox, or cholera, would alone outnumber the surgical total of lives saved. The same opportunity is not afforded by surgical affections, few of which are in any degree communicable. Again, the problems of medicine are slowly worked out. But the fruit of this silent and unremitting work will not suffer in the end through the delay. In reviewing the whole subject we may classify the infectious diseases in three groups: (1) the extinct diseases; (2) the diseases known to be preventable and which might be extinguished by present methods if carried out more stringently; and (3) the diseases of which the spread has been considerably limited, but which we cannot hope to completely suppress. The first group is a small one, but its mortality was great. It comprises in this country only malaria, typhus fever, relapsing fever, cholera, and leprosy. In the second group we can only mention small-pox and hydrophobia. Their suppression might be brought about if the proper means were adopted. The third is the larger group, made up of typhoid fever, diphtheria, scarlet fever, and the minor exanthems, whooping-cough, mumps, and the septic infections. Its record is less brilliant. Persevering efforts at segregation and disinfection may ultimately succeed, but the practical difficulties are great. In the vast field which remains outside the acute infections two of our national diseases, rheumatism and phthisis, stand out prominently, both of them now well in hand, the one thanks to treatment, the other thanks to prevention.

The diminution in the prevalence of phthisis and the measures of prevention.—In phthisis the combination of two infections, the specific bacillus and the organisms of suppuration, explains the need for the perfection of ventilation. There seems to be at last in this country, after a long and regrettable delay, an earnest resolve to provide this remedy. The first advance was made on the strength of general hygiene and in this direction the Factory Act led the way. The Royal Commission on Tuberculosis has reported a diminution of 27·9 per cent. in the period 1891–1895 as compared with that of 1851–1860 for the age-period 0 to 5 years. Great as this reduction is, it represents little more than half the reduction for the age-periods 15 to 20 years and 20 to 25 years. But under the special heading "Tabes Mesenterica" there has been a reduction of only 3·0 per cent. during the interval stated. The report points out that this result, which contrasts with the great diminution of tuberculosis at other ages, has coincided in point of time with the large increase in the consumption of milk. But we are now dealing more and more closely with the agent of the disease in its various modes of dissemination, in the sputum, in food, and in milk. The importance of the purity of the milk-supply has been revealed by the researches of Professor Delépine which are now leading to practical legislation. Since the tuberculin test enables us to detect disease in the cow before it has become otherwise obvious there is no reason why the spread of tubercle by milk should not be efficiently prevented. It should not be forgotten that it was Parkes who first authoritatively brought forward the treatment of the disease by hygienic and preventive methods. The essential of his views as to the management of phthisical patients was that they should be made to breathe an air as pure as the outer air without the danger of catching cold. But, as we are reminded by Dr. Tucker Wise,[1] another Englishman, Dr. George Bodington, in his essay on the Cure of Pulmonary Consumption on Principles Natural, Rational, and Successful (1839) was the pioneer of doctrines which have only gradually attained recognition.

The diminishing prevalence of the minor ailments and of trade diseases.—The increasing healthiness of the community is a notorious feature of the day and we need not review the long list of the general affections. More important are some of the "trade diseases" which modern hygiene has taken into its care and in which a distinct reduction has been brought about, as, for instance, in the destructive lung diseases from inhalation of dust and in the affections due to intoxication by lead, mercury, and phosphorus.

The prospect as regards the further limitation of disease.—With fewer diseases left to suppress are we likely ever to witness again a wholesale reduction similar to that which was the immediate result of the great advances in hygiene and pathology? The answer can hardly be doubtful. The material for future improvement is not likely to be soon exhausted; neither have we yet fully reaped the fruits of hygiene in the direction of prophylaxis and of an increased vital resistance to disease. Moreover, our weapons of attack are steadily improving. Discovery has almost become an

[1] THE LANCET, Nov. 26th, 1898.

Digitized by Google

organised function and its return of new facts may be expected with the same regularity as the output from a mine. One after another our parasitic diseases must yield to this never halting progress until sporadic instances of our more trivial zymotics come to be regarded with the same eager curiosity which draws a crowd of students round a stray case of typhus fever or of small-pox. Much disease of a non-infectious kind will also be prevented. If this is not too sanguine a forecast there can be but one conclusion—the ratio of instances of disease to the number of the healthy population must steadily diminish.

DISEASE CANNOT ENTIRELY DISAPPEAR.

There is, however, a finality in this encouraging prospect. Although we may in the distant future live healthier lives and die from old age some diseases must remain always. The most virulent diseases are those most easily prevented. But others are incapable of being suppressed and they are apt to be perpetuated by our success in saving the weaker lives.

The periods of life and their medical needs.—Though the decay of old age and the growth of the infant ought to be physiological processes this is almost the exception rather than the rule, and at both extremes of life a variety of affections call for medical assistance. Childhood and youth will remain obnoxious to various infective diseases but also to the ailments incidental to growth and development. The two dentitions, and particularly the onset of puberty, are times when medical advice must always remain essential. Among the minor zymotics which are not segregated measles is still prevalent and too often fatal and our inability to check the progress and the fatal results of whooping-cough is an opprobrium.

The affections of women.—Again, in women the climacteric periods, pregnancy, and child-birth, which should be purely physiological, need watching with special care and gynæcological practice must continue to flourish as it has done in the past.

The degeneracies of middle and of advancing life.—In middle and advancing life the later developments of syphilis will continue to prevail so long as neither the state nor science can cope with this scourge. Many visceral degeneracies are also traceable to infective disease, to wear and tear, to unevenly apportioned labour, and to the thousand risks of life, but most of them to human perversity in turning food and drink into poison. The dietetic diseases of the alimentary, the renal, the cardio-vascular, the nervous, the skeletal, and the cutaneous systems are likely to remain, like gout itself, more prevalent in this than in any other country in proportion with its growing prosperity and in spite of the wiser counsels now prevailing. Cancer abounds; how long will it refuse to yield up its secret and to respond to treatment? As to its alleged increase, some scepticism prevails amongst those best able to judge. But weighty arguments have been adduced in favour of its transmissibility.

Nervous diseases.—Abetted by syphilis and by the marriage of epileptics, these are not unlikely to become more prevalent; at any rate, their diagnosis is now more frequently made. We may distinguish three degrees in nervous disorders. Among the so-called *functional* affections we have hitherto recognised a purely functional group, including hysteria. But there is also a group of "neurastheniæ with degeneration" in which most of the symptoms are functional but in which either syphilitic or simple malnutrition overtakes the nervous substance. I need not dwell upon the remaining group, that of the common forms of central or peripheral *structural* disease. It is evident that the study of the neuron and of its many sufferings will long offer an ample field for pathologists and physicians.

Insanity prevails. Is its frequency increasing? This is not improbable. But, as with cancer, the statistics in the past have not been of a kind such as to enable us to compare the data with scientific accuracy. Insanity is more universally segregated than ever before, and the practitioner is on the whole little troubled with its treatment.

Nerve over-stimulation by drugs; drug diseases.—There is a source of nervous ailments entirely special to this age and the unexpected outcome of our nineteenth-century chemistry and advertising. Intemperance in drugs is becoming more common and it may possibly outstrip the abuse of alcohol and its evil results. The manufacture of new chemical products is supplying the public with endless carbon derivatives of high molecular power and of imperfectly known physiological action. Fortunately many advertised medicines are harmless, but their prolonged use is detrimental if only by delaying the treatment required by the original affection. Others are most dangerous, and their continued indulgence leads to confirmed neuroses or hopeless neurasthenia. Of this we all witness the daily demonstration. It thus comes to pass that as the therapeutic activity of the profession tends to abolish disease that of the public is manufacturing it.

Food diseases and infants' foods.—Whilst the increasing purity of natural foods has reduced our mortality modern ingenuity has been the unintended means of occasionally supplying poison in food. Fortunately ptomaine poisoning is an unusual accident. A much more serious and widespread evil has been the undiscriminating substitution by mothers of condensed milk and manufactured foods for the fresh supply of milk. This neglect of fresh milk and the untutored administration of artificial foods, even of the best kind, without due regard to proportion and to suitability, have been disastrous. To this cause may be attributed the fact that, in spite of modern hygiene, infantile mortality from diarrhœa and marasmus has shown no adequate decrease and sometimes an increase over that noted before these modern inventions.

The danger from the tropics.—Our chief danger in these times of rapid travel and traffic between the Old and the New Worlds is the importation of epidemics of virulent diseases as in the case of cholera of old and recently of influenza with its peculiarly lasting effects; and the plague is our present nightmare. But short of so calamitous an invasion we may expect a growing number of patients returning from the tropics with impaired health. The study of the tropical diseases is therefore most opportune, for not only must they call for a considerable staff of medical advisers in the newly developed centres, but their sequelæ cannot fail to require considerable treatment in this country. Short of the creation of a large and central hospital readily accessible from all the medical schools for the treatment and the study of these affections nothing would seem to be adequate for the fulfilment of our long-neglected imperial responsibilities, for the needs which coming years will multiply, and for the requirements of this vast metropolis viewed as the centre of an immense tropical empire. In conclusion, we may hope that our list of diseases is already complete and even though we might in future generations react differently to microbes which are now innocuous, our position, thanks to hygiene, will be safer than it ever was before.

THE PROFESSION AS IT IS AFFECTED BY THE LIMITATION OF DISEASE.

Although these remnants of disease keep up an excuse for our numbers there is no escape from a conclusion that the extinction of disease which has already occurred has perceptibly lessened our occupation. Those among us of maturer experience may be able to look back upon the field of practice such as they once knew it. Phthisis was enormously more prevalent than now. The zymotics flourished unsegregated, readily gaining entrance into houses and sometimes, like puerperal fever, dogging the medical man's footsteps, but once in possession were difficult to expel till all susceptible material had been used up; even small-pox was not uncommon because less segregated and less guarded against by revaccination; diphtheria and typhoid fever were unchecked in their spread; and the work of destruction by typhus fever was still active among the poor. But in addition those ailments were then rife with which we are still familiar; there certainly was not less of pneumonia or of bronchitis than at the present time, and diarrhœa and English cholera were assuredly more prevalent. Were the same progressive elimination of disease to continue at the same rate a time might be foretold when our ministrations would have become restricted to those two solemn episodes in the existence of our fellow creatures at which it is a wholesome tradition that the profession should be represented—the general practitioner being called in at the birth, the physician at the death; whilst most matters of health were prearranged from head-quarters by the man of hygiene in his laboratory. After its long and faithful stewardship is the profession to become in the distant future a parasite, a superfluous, purely ornamental profession—once active, now defunct? It may be safely predicted that this Utopian change will never be fulfilled.

OUR SCOPE OF USEFULNESS AND OUR OPPORTUNITIES IN THE FUTURE.

It cannot be gainsaid that this limitation of disease is an increasing factor in the pressure which is felt in the ranks of

Digitized by Google

the profession. Yet we need only look around to see that the medical men are neither fewer than they were nor unemployed. Habit rules supreme over us. In our social life, so persistently conservative, the set relations between employers and employed have a vitality of their own; there is a tendency to utilise agencies which the social system provides for use and the medical man continues to be consulted.

The anxieties of the educated classes.—Two modern developments tend to render him indispensable; both of these are the reflected results of the modern work and progress of science. I refer to the dread of disease and to the desire of prevention.

Leaving aside epidemics of virulent type, such as cholera, typhus fever, and small-pox, which struck terror in the land, the other zymotics, such as scarlet fever, measles, and whooping-cough, were regarded with an indifference bred of familiarity and of an imperfect knowledge of their possible results. But our labours in the suppression of disease have struck a new key. A wholesome dread, in some cases almost amounting to a panic, has seized upon the educated classes. The fear raised by the mention of scarlet fever might be thought immoderate but that it serves an excellent purpose both for the public and for the profession. As a result of this apprehension the medical man's advice is anxiously expected at a stage when formerly homely remedies were thought to be sufficient. The educated classes have also learnt another valuable lesson. They have now been roused to the idea of the preventability of disease and the medical man is often welcomed to conjure away its mere ghost. All round the wise doctrine is gaining ground that advice should be sought before harm has accrued. Although the attitude of the Eastern tribes in face of Kismet never existed among us too much was often left to chance. Nowadays we are approaching more closely to the type of that thoughtfulness for possible evils which prevails in transatlantic England where medical men are so largely consulted. Nor is this limited to the case of the zymotics, which isolation tends to remove from the sphere of private practice. The medical man is largely consulted for discomforts rather than for disease, for alarms rather than for ailments, most of them traceable to the too full enjoyment of the privileges of health and of the good things of this life. Thus, his attention is now drawn by the patient to a different clinical condition and this enlarging display of minor suffering may be one reason why nervous disorders are supposed to be more prevalent. Much of this might be regarded by sterner observers as due to imagination or to exaggerated sensibility. Yet there is a useful side to this minor form of practice. The medical attendant is afforded an opportunity for warning, and by his attention not only to the arrest and prevention of disease but to the improvement of the life and efficiency of the growing generation he does yeoman's service to the individual and to the State. A change, analogous in some respects, has come over the practice among the uneducated, although with results sometimes adverse to the interests of the profession. But the question of the provident system must be reserved for another lecture.

Our widening opportunities.—Enough has been said to show that our occupation is not gone but has shifted only and that our usefulness is as great in preventing as ever it was in treating disease. But in other directions also, including that of public health, important work awaits our highly trained students. A system of almost universal life assurance under State supervision analogous to that which has been largely introduced into Germany does not exist in this country, but if it were to become established among us it would make a considerable addition to professional work in connexion with the examination of candidates. Certificates of sound health and of freedom from contagious diseases and in particular from any tuberculous taint will be more and more in request as the public becomes more educated in matters of hygiene and more sensitive as to the risks of the dissemination of phthisis. For the selection of careers the profession is already largely consulted and the State exacts qualifying medical examinations for the services, but in this direction there is room for much more work than is at present done. The soundness of future generations and the exclusion of heritable disease are duties which may not be mentioned yet lie dormant near the conscience of the profession. The profession is not anxious to invite any responsibility of this sort, even if a tyrannically radical constitution, such as that of a Utopian republic, were wishful to exact it. Self-sacrificing and alert for the public weal in other directions it has on this point remained silent, and we may doubt whether the difficult question as to the discouragement of the marriage of the unfit and the yet more difficult question of the selection of the fittest are likely to be ever submitted to the profession for a practical solution, although there are those who would urge our being more outspoken and attempting even to create a public feeling on the matter. On the important subject of practical Malthusianism which is probably opposed by the conscience of the profession as a false notion politically, socially, and morally, its attitude has also been one of reserve. I believe it has always been in favour of the principles which are consonant with the best interests of humanity and with the greatest sum of happiness and power. Love of offspring is the healthiest sign of a race, and the national strength which is its reward stands revealed in connexion with armaments and now more than ever in connexion with colonising power. More advice will be needed by the State than has been hitherto taken, or at any rate acknowledged by it, in regard to ethnological and colonising questions—a mere sample of the large department of state work in which the profession is destined to take a share.

Compulsory education viewed in its medical aspects not an unmixed boon.—The medical supervision of education is another important question which affords considerable scope for professional activity. Where so many children are congregated and where parents are deprived of all means of selecting their associates a serious onus is incurred by the State and nothing short of the greatest care can cover its responsibilities.

The fatal transmission of scarlet fever and of diphtheria is the worst evil and the question arises whether everything has been done which might have been done to prevent their spread. Are all children who are allowed to return to their schools after an attack of diphtheria sufficiently disinfected in one of the most likely directions? The nasal cavities which are nearest to the seat of affection and in themselves often affected by the disease are too often forgotten as a persistent nidus.

The "head-evil" at schools.—But there is another evil, less serious in the eyes of the lay observer, yet fraught with most serious danger to health and even to life, which for many transforms compulsion into direct injury. It is since the children of the poorest have been forced into the Board Schools in the company of children of respectable and cleanly artisans that vermin have invaded homes carefully kept and the health, or even the life, of many a delicate child has been sacrificed. All this is preventable by insisting that the hair of all children under a certain age attending these schools shall be kept short. To the unthinking this may appear an unpardonable interference with the liberty of the subject, but I need not point out where really lie the crying injustice and the loss of freedom. Thus in matters of bodily health and in connexion with the danger of infection a great deal remains to be done which ought to be regarded as of urgent necessity. The examination of children as to their mental adequacy for the work of the school board schools is at last receiving attention and competent medical observers are now appointed to inquire into this question.

The medical attendance upon the healthy.—Princes have always had their body physicians and men of wealth have imitated the princes and given a social position often with little employment to members of our profession. In the days when Alexander received the ministrations of his faithful physician the rudimental knowledge then current must have provided little occupation for Philip during the conqueror's progress. How great and varied nowadays in personal matters and above all in matters of public health are the responsibilities of the physician to a potentate on his travels; and how much greater the forethought and provision in the case of armies—witness the recent expedition up the Nile—a campaign of hygiene, where one of the most important factors was the bringing on to the field of action, remote, difficult of access, and unhealthy, a large body of men in so efficient a condition that they could fight and conquer. This health-preserving function of the profession, of vital importance in the case of families, is becoming more widely utilised by the intelligent public and the same principle enters as an undeveloped idea into the scheme of the provident system where its further elaboration might perhaps help to correct one of the worst troubles of the profession.

Public health and sanitation.—A large field yet remains to be occupied in connexion with public health. From time to time some catastrophe directs public attention to the work which has silently been carried on. Meanwhile, from all parts of the country we have heard the same report as to the treatment meted out to the most useful man in the district. Finding this want of appreciation on the part of the constituted authorities can we wonder that there should be imperfect knowledge and appreciation elsewhere? Can it be said of every house that it is now medically inspected even once a year? Yet is any responsibility greater? Are all our public institutions adequately and frequently inspected? The Factory Act was the first attempt to deal with a frightful evil, but the same evil in less glaring proportions is still among us and it can hardly be said that the health and lives of thousands of city workers are protected in the way which any physician might indicate. This trenches upon matters which are semi-private and yet where many are employed there is a public duty to perform. Schools are generally provided with their own physicians and with them rests the ability to call in at proper times sanitary assistance. But turning to hospitals, do all of our hospitals possess a regular visiting health officer? It is now proposed at one of our children's hospitals to provide a staff appointment for a medical officer of public health and it is hoped that this example may find imitations. Lastly, even in the official work of local administration what do we find? Disaster and loss of life from the refusal to use the services which were offered as necessary for, or at any rate conducive to, safety. I need not remind you of what occurred at Maidstone.

THE CHANGES WHICH HAVE OCCURRED IN THE CONDITIONS OF PRACTICE.

Although, as I have endeavoured to show, there has been no falling off in the supply of work for the profession as a whole changes have occurred in its distribution, changes also in the conditions of practice, which have led to pressure upon the practitioner. This claims our notice all the more as it may be fairly said that never has labourer been more worthy of his hire. Whilst disease has greatly diminished treatment has grown and is on the increase and the labour of treatment is greater than at any previous time. This is true both from the point of view of the general practitioner and also of the hospital physician or surgeon. The details of treatment are amplified and require more minute care. There is in many cases not only a patient but a nurse to direct, her attendance and skill rendering many measures possible which without her could not be applied, and thus a great deal more is attempted and achieved. The sick room is a busier field and the medical man's call is not a mere formality or wasted in conversation. Hospital physicians and surgeons realise in a special degree this change. A quarter of a century ago it was not considered necessary for them to attend more than two or three times a week and they could then perform their ward duties within a moderate time. During their visit there seemed to be ample leisure for clinical discourse and this doubtless was a charm attaching to conditions of greater ease than now prevail. But the work is now, both for the physician and for the surgeon, so anxious as to render their daily attendance almost indispensable in the interests of the sick.

I am informed by those of mature experience that the conditions of general practice have considerably altered within the memory of living man and particularly within recent years. In the first place the attendances upon invalids are less protracted owing to modern methods and in this the patient is greatly the gainer. But this curtailment is sometimes due to the action of the patient.

The restlessness of patients and specialism.—It is undoubtedly one of the characteristics of the age that there is among us less inclination to bow to authority and on the part of patients or their friends to accept without question or reservation the *dicta* of their once trusted adviser. In the behaviour of those who are compelled to consult us there is to be noticed a restlessness in their desire for the advice of various authorities and a corresponding instability in the relationship between the patient and his medical adviser which is much to the disadvantage of both. There is an old saying that "it is much easier to treat the patient than to treat the patient's friends" who often speak with an assurance about medical matters which is generally proportionate to their ignorance of the subject and which it is particularly difficult to overcome. Friends have been known in their misdirected zeal to interrupt satisfactory progress by suggesting new methods and new advisers, both probably imperfectly suited to benefit the patient. Formerly the family attendant felt secure and from his knowledge of antecedents and of circumstances reaching back for a generation or more was in a position to act with more certainty than a practitioner casually called in. Sad, and in our experience not infrequent, are the cases where a patient who needed only to trust and persevere on the well-considered lines which had been laid down is passed from hand to hand with little chance of benefit and without any chance of carrying out the systematic treatment which is necessary. Much better had he desired his own faithful adviser, as difficulties arose, to seek the help that in his opinion was most likely to be of service. In this way the field of practice has been lessened for the family attendant, often to the detriment of the patients. But other causes have also led to a diminution of his opportunities. The concentration of study upon definite departments of practice has been peculiar to the last decades of this century. It has been an essential condition for progress and has worked beneficially for the profession and the public. But in this matter there is one essential element, that the specialist should continue at the same time to have competent general knowledge. Medical education as it is now understood tends to that happy result. Too often the patient is misled as to his own troubles; and his most obvious symptom, that which attracts his attention, may be but a small part of the case. Nothing will satisfy him till he has had the opinion of someone who has a reputation in reference to the particular symptom which has caught his attention, and this is a process apt to be repeated indefinitely. By the concentration of the specialist's observation upon this prominent symptom the important and essential elements of the case may pass unnoticed—a risk capable of avoidance had his adviser familiar with his conditions been at hand to reveal the less obvious essentials to a complete diagnosis. The patient's advantage lies in a coöperation between his regular medical attendant and his occasional adviser and this also works for their advantage and comfort. The cultivation of this mutual professional intercourse tends to strengthen the bond of professional brotherhood and well might we say, in the words of a great physician, "When doctors differ who shall decide? but when doctors agree who shall venture to differ?" This reminds us that combination is that which we must look to to ease many of our difficulties and it is a remedy which brings with it pleasure as well as strength.

ABSTRACT OF

The Morison Lectures

ON

THE RELATION OF THE NERVOUS SYSTEM TO DISEASE AND DISORDER IN THE VISCERA.

Delivered before the Royal College of Physicians of Edinburgh on Nov. 7th, 9th, and 11th, 1898,

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,

PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL AND CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

LECTURE I.

Delivered on Nov. 7th.

THE PATHOLOGY OF VISCERAL INNERVATION.

SIR JOHN TUKE AND FELLOWS,—In selecting so large a subject as the relation of the nervous system to visceral disease and disorder I need scarcely state that I had not the presumption, in view of the audience I should have the honour of addressing, to entertain any intention of an exhaustive treatment of material concerning which many of my hearers would be in a position to be, as some of them possibly have already been, my teachers, but rather to indicate so far as I could guiding points in a subject of

Digitized by Google

increasing interest and importance; to endeavour, in short, to discover principles—*principia*—those light rays of the dawn, the first perception of which in obscure surroundings is one of the most exalted pleasures of which the human mind is capable. In considering some features in the anatomy and physiology of the visceral nervous system in this place last year the method pursued was centripetal. We examined the subject from the so-called peripheral nerve-endings in organs to their known or surmised origin in the intermediate or central portions of the nervous system. In referring to some points in the pathology or pathological physiology of the same structures I propose following the same course. The pathology of the visceral nerve-ending may be frankly stated to be non-existent, although it may legitimately be assumed to participate in the disintegrative changes which may affect visceral nerve trunks and to which I shall presently refer. We have seen how difficult it is in many cases and under the most favourable circumstances as to freshness of tissue to detect the nerve endings in the viscera anatomically, and when we remember that some of our best histological methods such as the chrome-silver methods are not at present well adapted for pathological work, and that such investigations themselves require an amount of time which is not at the disposal of many general pathologists, it need not surprise us that the pathological changes in the nervous periphery are still in great measure a *terra incognita*. The recent tendency of physiological thought, moreover, to rob the peripheral visceral nervous system of the very modest amount of subordinate automatism claimed for it is calculated to delay active research in this direction.

The disintegrative changes in the visceral nerve trunks may be broadly regarded as of an active and passive kind, the former being due to organic or inorganic poisons and the latter to slow or rapid solutions of continuity by pressure or grosser traumatism. The organic poison playing the part of a morbific agent may be introduced or of home growth—it may be heter-intoxicant or aut-intoxicant. The heter-intoxicant organic poisons most frequently operative are alcohol and the infectious or contagious fevers, especially diphtheria; the aut-intoxicant some form of cacometabolism such as diabetes or gout. The most common inorganic poisons which are of necessity introduced and heter-intoxicant are lead, phosphorus, arsenic, and mercury. The specific effect which these poisons have upon the peripheral nervous system is to cause a proliferation of the connective tissue of the sheaths and of the nerves themselves and thus apparently by the accumulation of adventitious products to disturb the nutrition, impede the conductivity, excite in sensory nerves the sensibility, and ultimately to destroy the continuity of the axis cylinders of the affected structures. This process produces in short an acute tumour which rapidly invades the structure, eliciting in some cases its responsive properties and finally abolishing the latter. Fortunately the cessation or withdrawal of the morbific agent and the reparative power of nerve tissue drawing its life from a higher source serve on the removal of the proliferant and disintegrative blockage to restore the nerve in many cases to its pristine activity or to a state of sufficient functional power.

These well-known features of peripheral neuritis in general have also been found to apply to the visceral nerves, although having to deal in this case with structures differing largely in important anatomical particulars from the somatic series there would appear to be some modification of the process in the internal organs and the whole subject still constitutes one of the fruitful fields of future pathological research. Paul Meyer[1] in his account of one of the most carefully examined cases of diphtheritic paralysis with which I am acquainted found the degenerative changes referred to well marked only in the coronary of all the visceral plexuses. The pulmonary and gastric plexuses were doubtfully implicated and the semilunar ganglion and sympathetic system generally showed no distinctly pathological alterations. He concluded that the fibres involved in the coronary plexus were probably of vagal origin. The clinical visceral phenomena of diphtheritic poisoning, although in their most tragic form frequently associated with cardiac failure, are not, however, as we know, restricted to that organ and it is probable that like changes occur especially in the medullated nerves of other viscera. The severe pain of lead colic which Ross[2] considers neuralgic, as well as the agonising enteralgia associated with specific and old malarial poisoning in some cases, point to an irritative neuritis of sensory visceral fibres. The difficulty of detecting changes in the sympathetic system as a whole is doubtless due, as some have remarked, to the preponderantly non-medullated character of the nerves in question. The sensory nerves in the distant periphery are, however, according to Kölliker, usually medullated,[3] and in these the alterations attendant upon degeneration ought to be capable of detection.

The more gradual pressure exerted upon nerves by morbid growths, while it is conceivable that in some cases it may induce neuritic changes similar to those already referred to, may by the slow obliteration of nerve paths produce a disintegration more allied to the well-known consequences of nerve section in which the disintegration of the medullary sheath is more general and is associated with a minimum of thecal proliferation. Martius in his monograph on tachycardia[4] refers to a case under Hayem's care in which pressure by a sarcomatous tumour in the mediastinum induced atrophy with fatty-granular degeneration of the myelin sheath in both vagi and likewise mentions a case (p. 68) under Billroth's care, published by Kappler,[5] in which that distinguished surgeon excised a portion of the right vagus nerve in a man without permanent effect upon his heart's action, but with persistent paralysis of the laryngeal muscles innervated by the cut nerve, which doubtless exhibited the sectional disintegration of which mention has been made, although this is not expressly stated by Martius. Such processes destroy the activity of visceral nerves and are distinctly destructive, death-dealing, or pathological. The increased demand made upon the functional activity of an organ from breakdown in a system of which it is part, such as the demand made upon the muscular power of the heart when the circulation is from any cause rendered more difficult of maintenance, may, however, be regarded as constructive, life-giving, and physiological, although the organ manifesting compensatory power cannot be regarded as a typically normal one.

It has appeared to me to be permissible and a matter of sufficient interest to again examine a question which has already occupied the attention of some whose names will ever be held in honour by us. I refer to the relation of an hypertrophied organ to its nerve supply. A study of affections of the heart has impressed upon me the importance of this subject and I have chosen the uterus, as the organ manifesting greatest variation in physical bulk, as that best calculated to furnish data for the determination of the question, although, as I shall remark later, both this organ and the heart have intrinsic peculiaritiee not altogether shared by organs which do not possess the same range of rhythmical variation in capacity. William Hunter appears to have been the first to "suspect"[6] that the nerves of the gravid uterus were enlarged in proportion to the vessels. John Hunter[7] disputed this assertion and declared himself an unfaltering Hallerist so far as the nerves were concerned. The matter seems to have been regarded as more or less debateable until the acceptance by a considerable number of leading men of the published results of Robert Lee's work.[8] In more recent gynæcological literature the matter is not referred to very frequently, but Galabin's position may probably be regarded as that of the majority of authorities in that department of medicine. "It is now established," he writes, "that, as might have been expected, growth does take place in the nerves, including the so-called 'ganglion cervicale uteri,' to fit the uterus for the process of labour, in which both reflex action and periodic centric discharge of nervous energy play important parts."[9] The question, it will be gathered, was one not easy of determination and also eminently calculated to be embarrassed by the influence of preconceived notions. Lee asserts that William Hunter never dissected the non-gravid uterus and could not, therefore, have been in a position to institute a comparison. That great man, however, merely expressed a suspicion. The method of Lee, moreover, was open to fallacy. The ganglion cervicale uteri is not an unyielding structure and a good deal of adventitious tissue surrounds

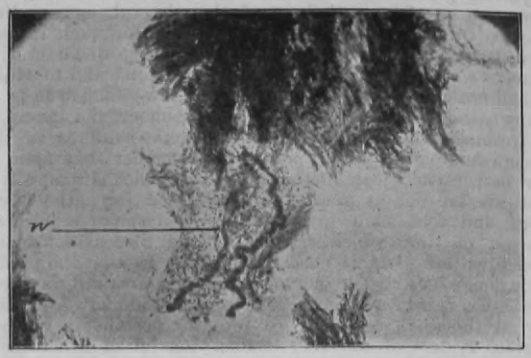
extra organic nerve-trunks. Nerves and ganglia may be flattened without notable intrinsic overgrowth.



To avoid these sources of fallacy I resolved to examine the nerves of the uterus at various stages of pregnancy by transverse sections of the lower segment where the nerves are largest and by longitudinal section and other means the body of the organ where the nerves naturally are diminished in size and less easy of detection and comparative measurement on transverse section. Sections of the lower segment were stained with hæmatoxylin in the usual way, while the nerves of the upper portion were examined by Sihler's method which I described last year. The animal used was the cat, and as I altogether failed to discover an adult animal which was not more or less pregnant one was kept for twenty-two days after parturition to allow of the uterus regaining its non-pregnant size and was accepted as the type of that condition. The animals were killed before examination by chloroform, hydrocyanic acid, and by drowning after having been anæsthetised. In gauging the size of the nerves at a given level the largest nerve visible was sought as that most easy of detection and least liable to erroneous observation. A large number of sections were made and examined more or less carefully. The general impression conveyed by these to my mind is reproduced in the following micromillimetric measurements actually made:—

—	Cervix.	Level of bicornu.	Body.
	Micromillimetres.	Micromillimetres.	Micromillimetres.
Advanced pregnancy: fœtus nearly fully grown	8 to 10	5 to 10	6
Early pregnancy: fœtus measured 1·5 millimetres	8 to 12	10 to 12	3 to 4
Twenty-two days post partum	7 to 10	5 to 7	5

As I have stated only the largest measurements were taken. Below these every size of nerve down to the terminal fibrils and penultimate plexuses were observed and to peculiarities of the latter I shall have to return when discussing visceral pain in the next lecture. The present observations on the relation of size of nerve to hypertrophied organ were indeed made *en passant*, the research being directed more to the elucidation of the local causes of visceral pain with a view to the discussion of the etiology of angina pectoris. In estimating the value of the measurements given three questions have to be answered: (1) were the animals the same size? (2) were all the measurements taken from uterine nerves proper? and (3) do the comparative sizes given in the three animals represent corresponding levels? The first and second of these questions I answer in the affirmative. The third requires some explanation as to the diameter of the nerve from the body of the uterus post partum. The body of the uterus in this condition being smaller than in early pregnancy and much smaller than in advanced pregnancy the whole of it was sliced with Cathcart's freezing microtome prior to staining, and it is possible that the nerve of comparatively large diameter noted as the largest seen in this case may have been obtained from the body of the uterus at rather a lower level than the mid-body—the portion examined in the other cases—and thus be somewhat of an over-estimate for the non-pregnant state. An examination, however, of the diameter of nerves in the cervical portion of the uterus leads to the conclusion that while there is practically no difference between the size of the uterine nerves in advanced and early pregnancy there is a certain increase of size to be noted in these conditions as compared with those in the quiescent uterus twenty-two days post partum, and it may therefore be validly assumed that what is true of one part of the organ is true also of the whole and that some increase in the *apparent* size of the nerves in the gravid as compared with the non-gravid uterus may be conceded. The increase is, however, I believe, apparent rather than real, for a closer examination of the individual fibres constituting the nerve trunks reveals no increase in them either in size or numbers. What may, however, be observed is a somewhat greater pliability and looseness or succulence of texture, the bearing of which upon the remarkable condition I shall presently refer to will be apparent. It may therefore be safely asserted that if any increase takes place in the size of the nerve of the gravid uterus it is in no sense proportionate to that which is by common consent met with in the case of the vessels, muscular fibre, and connective tissue constituting the organ.

Lee states that John Hunter left no preparations of the uterine nerves in support of his assertion that there is no increase in the size of the nerves of the gravid uterus. That matchless observer, however, left a positive assertion of an

FIG. 1.

N marks nerve-loop from the body of the uterus of a cat in early pregnancy.

observable condition and it requires some boldness to call in question the accuracy of his observation. Personally, I respectfully tender my adhesion with the qualifications already stated to John Hunter's statement as regards the condition of these nerves in pregnancy. But the difference between a statement of facts in an observable condition and the expression of an opinion, however positively made, which is not covered by those facts is very considerable. Science knows no *ex cathedrâ* utterances and the humblest who can draw from the bosom of

FIG. 2.

N marks nerve from the body of the uterus of a cat in advanced pregnancy.

nature an indisputable fact which contravenes the opinion of the most exalted not based upon such adduces a more mighty argument for his position than volumes of hypotheses backed by the sign manual of sacrosanct authority. John Hunter said that the uterus might be fifty times as large in pregnancy as in non-pregnancy; that all the textures of the organ are increased in size except the nerves; and that therefore the nerves have nothing to do with the action of the enormously overgrown organ. Hunter was not much of a casuist or he might have been more careful on this occasion. If, however,

Digitized by Google

the uterus be fifty times as large when gravid as when not gravid, and the muscular fibres of the organ can be shown to be innervated like all other muscular tissue somatic and splanchnic, what becomes of the innervation of the uterine muscle most distant from the point of entrance of the nerves at the cervix if these nerves do not enlarge? Do they snap in the stretching? To ask the question is to insult nature. Is there, then, any provision for the adequate innervation of the gravid uterus without an anatomical increase in the size of the nerves in that state? There is, and a provision which to my mind is one of the most remarkable as it is one of the most simple conceivable. The simple and sufficient expedient adopted by nature under the conditions discussed is one which was unknown to me when I undertook this investigation and I am not aware that it has been described before. Tortuosity in the blood-vessels of the uterus from their notable increase in size is more apparent in the gravid than in the non-gravid organ. Tortuosity of the uterine nerves is, I believe, inversely as the size of the organ. Tortuosity of nerve-trunks may indeed be seen in the fully gravid uterus, but in none of the sections of the organ at term which I have examined have I observed by any means the same degree of tortuosity and coiling as in the nerves of the uterus in early pregnancy or post partum. This coiling may, indeed, be such (as in one specimen which I show) as to suggest the figurative parallel of paying out a coil of rope to an object which is increasing its distance from a point of attachment. In the facts I have mentioned and the specimens I show I believe I have grounds for maintaining that it is by this grandly simple expedient that the nerve supply of an organ intended to vary in size is adapted to these varying circumstances. The apparent increase in the size of the nerves, their more open texture, their more succulent appearance, are but adjuvant conditions which promote the paying-out of the nerve-rope to the lengthening organ. When we come to examine the relation of the cardiac nerves to angina pectoris in the next lecture the bearing of these facts upon a wider range of physical conditions will be more apparent. The nerve-coil is, however, but an emphasising of that wavy elasticity which the longitudinal section of any nerve with a considerable range of extensibility—such, for example, as the pneumogastric—will show.

The conclusions, therefore, to be drawn from the facts I have stated as regards the anatomical relation of the nervous system in a physiologically hypertrophied organ possessing a considerable range of normal variation is that there is no essential increase in the proportions of such nerves to such organ, but that anatomical and physiological changes occur in the nerves which enable them to adapt themselves to the organ they supply and in a measure control. As Galabin states in the passage I have quoted "both reflex action and periodic centric discharge of nervous energy play important parts" in the process of labour. With essentially centric conditions I am not at present concerned. My present purpose is to suggest that one of the factors in evoking reflex action at term and in inducing those contractions associated with pain referred to the active viscus, under these circumstances, is the fact of the enlarged organ having reached at a certain period the full tether of its intrinsic nervous system. The rope has been paid out to its full convenient stretch and the note is sounded for a return of the organ to more moderate dimensions. There is a crudeness about this suggestion, I admit, which at first repels one, but having carefully thought the matter over, and without wishing to impute an unduly prominent *rôle* to this factor in the production of labour I can come to no other conclusion. The predisposition to centric discharge, as Galabin calls it, is doubtless induced *pari passu* with the changes I have indicated, but I do not think that the factor named can be eliminated.

Robert Lee[10] maintained the same thesis in connexion with the nerves of the heart when that organ is hypertrophied which he did in the case of the gravid uterus. His words are: "That the ganglia and nerves of the heart enlarge like those of the gravid uterus when the walls of the ventricles are affected with hypertrophy." Cloetta, quoted by Walshe,[11] partly agreed with Lee, but could not decide whether the apparent increase in the size of the nerves was due to an increase in the connective tissue sheath or to actual increase in the nerve fibres. These assertions have not so far as I know stood the test of time, although I am unaware of any systematic examination of the question. In view of the facts I have stated in connexion with the innervation of the gravid uterus and which are opposed in great measure to Lee's conclusions I should, *a priori*, dispute the correctness of his views as regards the innervation of the enlarged heart. There is, as I shall endeavour to point out in my next lecture, a special provision in the nervous anatomy of the heart, the same in principle as that met with in the uterus and to which I have referred, for allowing the nerves of that organ, which varies so much in size during action, to adapt themselves to such variation. This provision is less marked in organs such as the spleen and the kidney with a smaller range of normal variation in size.

Leaving nerve trunks I pass now to some mention of the pathology of the ganglion and the ganglion cell in the visceral nervous system. Death, that universal law which organised matter must obey and which has been suitably defined in scientific language on the tomb of Bacon at St. Albans as the command "Let compounds be dissolved," induces changes in such compounds, changes observable and yet not truly pathological, as we usually understand the term, but which may be mistaken for such. The criteria for their satisfactory discrimination from pathological changes cannot yet be said to have been determined. To grow old is in a manner partially to die; to be enfeebled is likewise a retrograde change. Advance in life, however, is not pathological; enfeeblement is, and yet changes may be met with post mortem in the cells of old and young alike which are at times difficult to distinguish the one from the other. This confusion between dead young and old tissue is not, however, I think frequently possible. Collateral conditions serve to distinguish the one infallibly from the other. The features of senile degeneration in ganglion cells mentioned in one of the most recent and reliable works on diseases of the nervous system[12] are a certain diminution in size and number of cells and well-marked pigmentation, such pigmentation not being associated with notable disorder of function. When changes normal to senility are found in youthful cells it is highly probable that the latter have been rendered functionally old by disease and that the change must be regarded as pathological.

In writing of the changes met with in the cardiac ganglia Ott[13] states that two kinds of pathological change occur in these—the one progressive and consisting of hyperplasia of connective tissue and the other retrogressive and consisting of parenchymatous degeneration of new cells. The former he met with in congestion and hypertrophy of the heart; the latter he found associated with qualitative blood changes such as uræmia and pyæmia. The proliferation of connective tissue in a visceral sympathetic ganglion may, however, be of a more active type, as was shown by Lancereaux's case[14] which so long reigned alone as an instance of cardiac neural pathology. In this case the cardiac plexus participated in an extremely rich abnormal vascularisation at the root of the aorta and showed microscopically a round-celled infiltration between the nerve fibres of the ganglion which compressed the former. These conditions were associated with angina pectoris. But the progressive and retrogressive changes may be met with in the same case. A ganglionic structure may participate in a general interstitial proliferation such as that met with in granular kidney. Although it may be difficult to decide whether the parenchymatous change in the nerve cell be due to such interstitial hyperplasia, or both it and the latter be the expression of a blood dyscrasia causal of each, the influence of interstitial cirrhosis in interfering with the due nutrition of a nerve centre cannot, I think, be altogether excluded and may even be causal in some measure of the changes in question. Such changes need not, however, place the cell out of action, although it is highly probable that the functional activity of such a cell is subnormal. This combination was well shown in a posterior root ganglion which I examined last year and which I obtained from Dr. Risien Russell, pathologist to the National Hospital for the Paralysed and Epileptic, Queen-square. The case had been under the care of Dr. Hughlings Jackson, to whom I am

indebted for permission to refer to it on this occasion. The necropsy on this patient, a male, sixty-five years of age, took place six hours after death. The nervous system revealed nothing abnormal beyond an atrophic state of the convolutions of the hemispheres generally and the central vessels were atheromatous. The kidneys presented the typical contracted granular appearance associated with the changes of interstitial nephritis and the heart the corresponding condition of concentric hypertrophy. A posterior root ganglion which I examined by various methods showed well-marked interstitial hyperplasia like that characteristic of the general state in which the body was, and parenchymatous change in a large number of the nerve cells. This change would, I presume, be termed pigmentary, but as the degenerated portion stained very darkly after exposure to bichromate of potash, osmic acid, and nitrate of silver, which had no effect upon the rest of the cell substance, a fatty degenerative change would appear to have been present. I show lantern slides from the preparations in illustration of these points. To compare with these atrophic and proliferant conditions I also show the state of a posterior root ganglion from the body of a female, eighteen years of age, who died in Queen-square Hospital from double pneumonia due to mastoid disease without central nervous complications. The case was under the care of Sir William Gowers and the ganglion examined was given to me by Dr. Risien Russell. The differences between the old degenerate ganglion associated with arterio-sclerosis and general interstitial hyperplasia and the normal organ of a young person who practically died an accidental death are very striking. The large, better differentiated cells with little parenchymatous and no interstitial change in the young and normal ganglion are easily distinguishable from the ganglionic cirrhosis and degenerated cells of the decrepit old man.

It is only necessary to refer to two other conditions of the posterior root ganglion, those, namely, associated with herpes zoster and dorsal tabes. Atrophy and induration have been found in the posterior root ganglia related to territories of skin affected by herpes zoster, the agonising pain in many cases of which affection is so well recognised a clinical fact, while in dorsal tabes an inflammatory process, chiefly affecting the proximal and central portions of the posterior root ganglion and the posterior root itself, has of recent years attracted growing interest and attention. These changes are described by Leyden and Goldscheider as atrophic[15] and affecting the nerve fibres. The connective tissue is also said to be increased, but the question of a change in the nerve cells is left undecided. The admitted alterations are, however, of interest in connexion with the sensory disorders of the viscera with which we shall be engaged in the next lecture, and particularly with the visceral crises of tabes which have so pernicious an effect upon the course of the disease. Our knowledge of the course of visceral fibres in the central nervous system is still so limited that a discussion of the pathological lesions associated with general trophic degradation would not at present be useful. It is a very remarkable fact how little most central lesions outside the bulbar area are accompanied by such general atrophy. The two factors in chronic diseases of the central nervous system which appear to bring about malnutrition most rapidly are pain and mental anxiety, and the latter may be regarded as pain in the intellectorium just as the condition we conventionally call pain is a reaction in the sensorium—to use old terms largely and perhaps prematurely discarded. Inasmuch as physical degeneration will be brought about by these conditions in the absence of central lesion we cannot well gauge the influence of the latter, but it is rational to think that their presence hastens and emphasises the malign influence of pain and mental distress.

It will thus be observed how rudimentary our knowledge of the pathology of the visceral nervous system still is. There are, however, already hopeful evidences of light-giving work in this obscure field and I cannot close this lecture without a passing reference to those histo-physiological investigations which have brought to light interesting facts as regards the behaviour of nerve cells cut adrift from peripheral organs with which they are normally associated. The changes, although purely physiological, appear to point to a method of research which may lead to knowledge of pathological change in cells whose touch of the organs they innervate may be loosened by disease general and local. Although I have myself undertaken some work on these lines my work is still incomplete and for the information on which my few present remarks are based I am indebted in great measure to Van Gehuchten's exhaustive paper on the Fine Anatomy of the Nerve-cell in "La Cellule,"[16] in which also full references to the very interesting literature of the subject will be found. It would seem to be essential to the maintenance of healthy structure in the nerve cell not only that it should itself be undamaged but that the organ its axis cylinder more or less directly innervates should also be in a condition healthily to exercise its function. This is surely a very suggestive fact as regards the relation of body and mind, the subjective recognition of which is at least as old as Juvenal who associated the sound mind with the healthy body. The functional unit, in short, as we shall argue again, is not one but triune—peripheral organic cell, central nerve cell, blood. Our knowledge of the general effect upon the central nervous system of the severance of the periphery from the centre is as old as the researches of Bérard, Vulpian, and Dickenson (1829–66), quoted by Leyden and Goldscheider,[17] who studied the effect upon the cord of the amputation of limbs; but our more exact knowledge of details in the process is much more recent and due in great measure to the method of staining nerve cells introduced by Nissl and which has already been fruitfully applied to the examination of normal and abnormal conditions of cells in the central cortex. Van Gehuchten's observations were made upon the hypoglossal and pneumogastric nerves of the rabbit, the latter nerve being divided below the plexiform ganglion. The changes noted in the medullary nuclei of both nerves were—(1) a chromatolysis during which the chromatic granules in the cell protoplasm were dispersed towards the periphery of the cell, the protoplasm staining soon afterwards a uniform blue; (2) an eccentric displacement of the nucleus which might proceed to extrusion and the consequent sacrifice of the cell; (3) in the case of motor cells a gradual recovery at least for the time to their original chromatic or "pyknomorphic" condition was noted, while the sensory cells in great numbers disappeared absolutely. More recently Goldscheider and Flatau[18] have studied changes induced in cells by various poisons of an organic and inorganic nature. Their results with the use of tetanus toxin are particularly interesting, as also the effects they have observed to follow from the exposure of animals to high temperatures. There appears to be a very noticeable enlargement of the cell nucleus in tetanus and a complete chromatolysis seems to be induced by excessive temperatures. This sketch of the changes, pathological and experimental, met with in the visceral innervation shows how little is as yet positively known of the alterations which underlie neuro-visceral disorders; but it likewise declares plainly that the night is past and that daylight more or less clear cannot be very long delayed.

THE SPECIFIC ORGANISM OF VACCINIA.

BY A. F. STANLEY KENT, M.A. OXON.

IN a former issue of THE LANCET[1] I gave some account of certain experiments upon the nature and cultivation of the virus of vaccinia. It is the object of the present paper to give a further account of these experiments and to describe the results subsequently obtained.

To recapitulate very shortly the main points of the former researches, it will perhaps be remembered that the starting point[2] was the histological examination of sections of the vaccine vesicle at various stages of its development, the significant fact elicited from such examination being the presence in the tissues of an organism differing in morphological characters, in staining reactions, and in distribution from the organisms of the surface and from the foreign organisms ordinarily associated with vaccinia. It is of course a by no means difficult task to isolate from a material like vaccine lymph—which swarms with micro-organisms of various species—and to cultivate, some one or other of the

non-essential germs; indeed in this way much labour has been expended and much time wasted. And yet not entirely wasted, for though failing to accomplish the primary object of determining the nature of the actual contagium such researches have cleared the ground and have facilitated the work of subsequent investigators.

It is nevertheless somewhat remarkable that claims to be the specific virus of vaccinia should have been put forward in the case of several organisms whose sole title to the honour appears to be that they occur in vaccine lymph. How little this latter fact is in their favour will be appreciated when the long list of bacteria having similar claims is called to mind. It is by no means impossible that there may have been some justice in the contention put forward that certain of these organisms played an important *rôle* in the processes of vaccinia; nevertheless, it was impossible that the real virus of the disease—the organism in whose absence vaccinia could not occur—should be discovered and its identity put beyond question until the actual direct proof by cultivation and inoculation could be brought forward, and in every case until recently the direct proof has been wanting. There appeared, however, to be some facts in favour of the organism which I discovered in the tissues of the vaccine vesicle in 1894[3] being regarded as possessing claims perhaps somewhat higher than those of the bacteria previously described to at all events a tentative recognition. The new bacillus was, in the first place, exceedingly minute, measuring a bare micron in length; it appeared to occur, as a rule, in pairs joined so as to form dumb-bells, not true diplococci, the individuals being distinctly, though only slightly, greater in length than in breadth. Further, the staining reactions were not such as are usually found in the case of ordinary saprophytic bacteria. Most important of all, however, was the fact that these minute bacilli occurred not on the surface or, so far as could be ascertained, amongst the crowds of foreign organisms in the most superficial parts of the vesicle, but deeply seated, in large numbers, and in practically pure culture in their special habitat beneath the line of incision. It is natural to expect to find the organism upon which a disease depends in the tissues of the affected animal, and the fact that this special organism not only conformed to this requirement, but was, in addition, apparently the only one of which this was true, rendered a thorough investigation of its nature desirable.

Regarding its occurrence in the tissues it will perhaps be recollected that in 1894[4] I showed microscopical specimens in which by a special method of staining its presence had been demonstrated. It was also pointed out that it closely resembled a certain organism which by following special methods had been demonstrated in vaccine lymph by Dr. Copeman and myself.[5] But the bacillus in the lymph appeared to occur especially in early lymph and, in fact, its presence in lymph taken from mature vesicles seemed doubtful. In the sections of the vesicles, on the other hand, the special organisms could always be shown to occur even up to quite a late stage of the disease, and their numbers were very great. To explain their apparent disappearance from mature lymph which nevertheless maintained its power as vaccine it was suggested that as time went on spores were formed and it was further suggested that these spores formed the material which conveyed the disease when the lymph was preserved dry on points. That this may occur is, I think, probable. Indeed, the appearances presented by the organism when stained in certain ways strongly suggests such an explanation. At the same time it is not improbable that the bacilli themselves occur in the lymph up to quite a late stage in the maturation of the vesicle. For if instead of collecting lymph in the usual manner by applying pressure forceps, removing the crust, and allowing clear liquid to exude a slightly different method is adopted and the pressure forceps being dispensed with the crust together with as much of the underlying tissue as possible is removed by means of a Volkmann's spoon, the lymph which exudes from the base of the vesicle will be found even in late stages to contain the specific organsm in large numbers. I believe the explanation to be that the bacilli occur in the lymph and in the superficial parts of the vesicle early in the disease but that later their distribution is altered and they lie more deeply in the tissues.

As regards the existence of spores in the diplo-bacillus it may be noted that a very large number of preparations has been made and new methods have been devised in the hope of demonstrating their presence, since the general behaviour of the lymph seems to be best explained on the assumption that they do actually exist. Up to the present, however, I have only occasionally been able to show certain spherical exceedingly minute bodies which so far as it has been possible to investigate them appear to be of the nature of spores, but whose minute size renders any certain knowledge of their nature exceedingly difficult to obtain, at all events with the instruments which I have at my disposal.

Regarding the bacilli themselves some additional information has been obtained. As is well known the foreign organisms which occur in vaccine lymph as ordinarily collected, and which have nothing to do with the specific properties of the lymph, exist for the most part on the surface, in the crust, and in the superficial parts of the vesicle. *The foreign organisms do not occur in the deeper parts of the vesicle.* Indeed, it is possible to obtain a very nearly pure culture of the specific organism by removing by means of sterilised instruments the superficial parts and subsequently taking material from the base of the vesicle. Many of the organisms so obtained will be found to be contained in cells and to correspond to those more deeply-lying individuals which I have described in sections. So completely have they taken possession of these deeper regions that it is no unusual thing in examining a series of preparations made in the manner which I have indicated to find cover after cover showing no organisms whatever except the diplobacillus vacciniæ, whilst that occurs in large numbers.

So far, then, as its distribution in the tissues has been investigated, the results would seem to indicate that the organism which I have described deserves to be placed upon a somewhat different footing from those which have been previously isolated from vaccine-lymph. With regard to its specific nature, however, it was of course impossible to come to any definite conclusion in the absence of any method of preparing pure cultures, and my efforts were in consequence directed towards elaborating such a method. How at last I attained success in my endeavours has been described in a former paper,[6] and since that paper was published a series of experiments has been carried out with the object of finding some new culture medium or some modification of the old which would allow a more rapid growth to take place than was the case with the mixtures at first employed. In my original culture medium of albumin and glycerine it was found that the best proportion of glycerine lay somewhere between 15 per cent. and 20 per cent. Considerable care has to be exercised in the adjustment of the proportion of this constituent, as on the one hand if the quantity present is insufficient the growth of foreign organisms is not checked, whilst on the other the presence of an excess of glycerine appears to exert a prejudicial effect upon the development of the vaccine virus.

The proportion of albumin in the mixture is also not without importance, for unless it is present in fair amount the glycerine appears to exert more than its usual power and so prevents a satisfactory growth being obtained. The exact proportions which I am at present employing are: albumin, 34 per cent.; glycerine, 16 per cent.; and sterilised water, 50 per cent. As regards this last ingredient I at first used distilled water, but subsequent experience proved that somewhat better results appeared to follow the employment of ordinary tap water. The exact nature of the salts present in this and their quantity I have not determined, but they seem to be rather beneficial than the reverse.

Another material which I have used as a culture medium with some success is milk—either whole milk or the liquid obtained by the filtration of whole milk through a Berkefeld filter—either mixed with a suitable proportion of glycerine or alone. The best proportion of glycerine to use appears to be about 33 per cent., and in such a medium I have obtained an active culture in somewhat less time than is required in the case of the glycerine and albumin medium. The milk media offer the further advantage that they can be sterilised by heat in the ordinary way without destroying their power of supporting the growth of the diplo-bacillus. I am at present making experiments with various other media, notably with the blood-serum of various animals, both mixed with glycerine and unmixed; and a material which has been provisionally tested with encouraging results consists of vaccine vesicle pulp freed from all organisms by the prolonged

[3] Loc. cit. [4] Loc. cit. [5] Loc. cit.

[6] THE LANCET, May 21st, 1898.

Digitized by Google

action of strong glycerine at a suitable temperature until plate cultivations show it to be free from foreign organisms and inoculation upon susceptible animals shows it to be free from the specific virus of vaccinia. This material when absolutely free from all organic life is diluted with sterile water to the required percentage of glycerine and used as a culture medium in the ordinary manner.

Another factor of great importance in obtaining pure cultures of the diplobacillus is the temperature at which the tubes are kept. In my earlier experiments the culture tubes were allowed to lie in the incubator at 37° C., but it was soon found that better results were obtained if a somewhat lower temperature were employed. It appears that even at 37° C. the glycerine when present in so low a percentage as 15 per cent. or 20 per cent. exerts an injurious action upon the virus and better results can be obtained by keeping the tubes at a temperature of 15° to 21° C., though a longer period of time will be found to elapse before distinct traces of growth appear.

The staining of the diplo-bacillus is a somewhat difficult matter and very slight causes seem to be sufficient to determine in any given instance whether the organisms will stain by a special process or will not. More especially any overheating in the flaming of the cover-glass preparations seems to be fatal to a good result, and often in such slides the diplobacillus may be seen to be quite unstained, whilst other bacteria if they happen to be present may have taken the stain strongly. Löffler's alkaline methylene blue has in many instances given me satisfactory results, but it must be allowed to act for a long time. Curiously enough in preparations stained with this dye the organisms are sometimes stained red—not a faint pink that might be attributed to the effect of contrast, but a brilliant saffranin red which is obviously due to some special reaction between the organism and the dye. I have seen similar phenomena before—some years ago in the case of an entirely different organism—but there a special part of the bacillus, possibly a spore, was stained brilliantly red, whilst the rest of its body was stained blue. At the time I attributed the difference in colouration to some difference in chemical constitution between the main mass of the bacillus and the spore-like body. In a different category must be placed the instances in which in Gram-stained preparations a difference in tint is discovered. Here we are dealing in the first place not with a pure blue but with a violet and in addition the decolourisation process may be held responsible for some variation in the result. Yet it is curious even under such conditions to observe that occasionally one member of a diplococcus may be violet whilst the other is pure red. In the case of methylene blue the change from blue to red is due to a process of oxidation and oxidising agents when added to a solution of the dye turn it at once to a brilliant red. Some such process would seem to take place also in the instance under consideration.

For staining sections I have found a modification of Gram's method the most satisfactory, used after the tissue has been hardened in absolute alcohol or in a mixture of Müller's fluid and a saturated solution of mercuric chloride in 1 per cent. acetic acid. Either of these hardening agents gives good results and the distribution of the specific organism, especially in the deeper layers, is well shown. For cover-glass films of lymph and cultures better results have recently been obtained by the employment of carbol fuchsin after the ground has been cleared in 20 per cent. acetic acid in the usual manner. If the fuchsin be allowed to act for from 15 to 20 minutes and the covers be then subjected to a somewhat prolonged washing in water preparations may be obtained which, though somewhat dirty in appearance and by no means "pretty" specimens, yet show the diplobacillus intensely stained and in parts quite free from granular material or stained ground. Even a short sojourn in alcohol removes the dye very completely from the organism.

Appearances presented by the cultures.—If, then, a culture medium is to be prepared it should contain about 34 per cent. of albumin and 16 per cent. of pure glycerine and the precautions taken in its preparation should be sufficient to ensure the absence of all, or nearly all, foreign organisms; or in lieu of such stringent precautions the albumin and glycerine may be mixed together in a pure state and kept until such time as plate cultivations show that all organisms have been killed out, being subsequently diluted with sterile water to the required strength. The inoculation of the culture medium should be effected by the employment of vaccine lymph (preferably taken from the base of a vesicle after the superficial parts have been removed by sterile instruments) which has been kept in contact with glycerine until on testing in plate cultivations foreign organisms are shown to be absent and on testing by inoculation upon susceptible animals the lymph is proved to be active. The quantity of seeding material used in my experiments has varied. In some recent experiments the proportion of lymph to culture medium has been 1 in 820,000, and the cultures, after having been established for little more than a week, have given positive results when inoculated upon animals. Usually, however, in cultures so prepared no visible change occurs during the first few days, especially if the tubes be kept at a low temperature. Afterwards the fluid is observed to lose its brightness and gradually a faint opalescence will develop until in a week or ten days the whole liquid will be distinctly turbid. At the same time a certain amount of a flocculent material will be separated and will fall to the bottom of the tube. In addition, examination will reveal the presence of a delicate white film on the sides of the tube and closely adherent to it. In this connexion it is interesting to note the fact, often observed in practice, that vaccine lymph when taken from the calf and sealed up in capillary tubes in the usual manner is by no means certain in its action if used for the vaccination of children within a short time of its collection, whilst if it be kept for some time its virulence is restored and if then used it is found to give perfect and uniform results. This fact has been explained by the assumed adherence of the particulate carriers of the disease to the sides of the tube and their later separation from it.

In the case of cultures made upon the whole milk media described the presence of the fat would of course interfere with the observation of the above changes. It will, however, be noticed that in such cultures the milk tends to lose its opacity and to become yellower, changes best seen when the fluid is examined in thin layers and by transmitted light. In addition a certain small amount of a chalky-looking deposit falls to the bottom of the tube. Plate cultivations upon agar and gelatin established from such culture-tubes as those described yield negative results—that is to say, after incubation at 37° C. and 21° C. respectively for a week the plates will show no points of growth and thus the presence of foreign organisms is excluded.

Inoculation of the cultures upon animals.—If, however, the material be used for the inoculation of susceptible animals such inoculation will in successful cases result in the production of vesicles indistinguishable from those produced in the ordinary course by vaccination with current lymph. Moreover, having once obtained a growth of the diplobacillus it is by no means difficult, though on account of the slowness of its growth it is a somewhat lengthy process, to establish from it subcultures which when used in their turn for the inoculation of animals give similar results. One difference in the action of current lymph on the one hand and of these early (ten day old) cultures on the other which has been commonly observed is that whilst with the former 100 insertions will, as a rule, produce 100 vesicles, with the latter a like number of insertions will produce perhaps only half as many. As time goes on, however, the insertion success improves considerably, and with cultures of three weeks old which in the early days failed to produce any result when used for inoculation I have frequently obtained exceedingly satisfactory results, the success ratio sometimes rising as high as 100 per cent. Further keeping for a period of from eight to ten weeks often results in a gradual decline in activity and sometimes at the end of this time formerly active cultures are found to be inert. This decline in activity seems to depend very much upon the temperature at which the tubes have been kept and it may be possible to preserve virulent cultures for considerable periods by adopting suitable precautions to protect them from excessive heat. The failure to obtain a higher insertion success in the case of early cultures I attribute principally to the difficulty which exists in so proportioning the constituents of the culture medium that on the one hand foreign germs may be prevented from growing and yet that the diplobacillus may thrive, for it is undoubtedly the case that glycerine, whilst exerting a less deleterious effect upon the vaccine virus than upon other organisms, yet when present in the higher percentages does exert such an effect upon it to an appreciable degree and exerts it very markedly at temperatures only slightly raised above that of the air. I hope to go more

Digitized by Google

fully into this subject on a future occasion. At present I wish merely to point out that it is a matter which has to be taken into account in the elaboration of a method of cultivation.

In the experimental inoculation of animals with the cultures of the vaccine virus described above the results produced have been sometimes quite typical and, indeed, indistinguishable from vesicles produced by current lymph. In others the vesicles, though typical and well formed where present, have not appeared along the whole of the line of incision, thus leading one to the conclusion that the culture, though active, was somewhat weak. It may perhaps be well, in order to convey some idea of the results ordinarily obtained, to give the record of a recent experiment as entered in my note-book.

Experiment.—Vaccine culture established in medium of—water 50 per cent., glycerine 16·5 per cent., albumin 33·5 per cent., inoculated with a vaccine lymph which had been preserved in glycerine until all foreign organisms had been killed out. The proportion of seeding material used was about 1 in 105,000. Two days later a calf was inoculated on the abdomen in a number of incisions. All the insertions failed. Five days later (the seventh day) it was examined microscopically. Groups of the diplobacillus were found. Four days later (the eleventh day) a calf was inoculated upon the abdomen. The incisions took and they produced typical vesicles in the proportion of 37·5 per cent. Lymph taken from these vesicles was used in the vaccination of a child. All five insertions took perfectly and presented typical appearances of vaccinia. Seven days later (on the eighteenth day) the culture was used for the vaccination of a calf. The incisions took perfectly and produced typical vesicles = 100 per cent. Lymph from the above vesicles was used for the vaccination of a child and produced good results. On the forty-ninth day the culture was used for the inoculation of a calf. When examined on the fifth day the animal presented no typical vesicles, but in the course of the lines of inoculation were certain shotty thickenings which seemed to indicate that some reaction had taken place. Upon revaccination with current lymph the animal proved to be insusceptible.

In examining the above record several points of interest present themselves. In the first place, it will be observed that the culture was a primary one—i.e., not a subculture—and it may be objected that such an experiment is valueless as the material used for seeding might conceivably give rise to the results obtained. I have, however, selected the experiment for that very reason as the facts appear to me to be sufficient to entirely exclude such an explanation. In the first place, although, as is well known, vaccine material may be diluted to a very large extent without entirely losing its power of giving rise to typical vesicles, yet when the dilution reaches 1000 times those vesicles are very few and far between, and when, as in the present instance, the dilution reaches more than 100,000 times the appearance of such vesicles is a very exceptional occurrence. Indeed a somewhat extensive series of experiments with lymph diluted in varying degrees has in my hands altogether failed to show any vesicle produced by a dilution at all approaching the above. Moreover, it will be observed that the culture in question when used for the inoculation of animals in the first few days of its existence *entirely failed to produce any trace of a vesicle.* Had there been any weight in the objection I have raised it would undoubtedly have been the case that the diluted lymph would have shown at least as great activity immediately after dilution as subsequently. That such was not the case is I think a strong argument in favour of a multiplication of the specific virus having subsequently taken place, and when it is recollected that the activity as shown by inoculation experiments increased from zero to 100 per cent., the evidence is almost conclusive. This gradual increase of activity is most significant, and I fail to see how it can be explained except upon the assumption that a multiplication had taken place. But the proof by no means rests altogether or even chiefly upon such evidence as the above. As mentioned before, subcultures are not specially difficult to prepare, and they show results in all essential particulars quite similar to those given by the primary culture.

Another very interesting point is in connexion with the behaviour of the culture in the later stages. It will be noticed that after its power of producing typical vesicles had become exhausted its use for inoculation upon an animal still gave rise to some local effect and, which is far more important, was able to protect against a subsequent inoculation with a virulent virus. By following up the indications given by such experiments as this it is not improbable that one may be eventually led to results which will render possible the immunisation of animals and human beings without the at present unavoidable concomitants of painful local reaction and unpleasant constitutional symptoms. I am at present following up these indications and I hope shortly to publish the results of my further experiments.

In estimating the success of the inoculation experiments I have not trusted altogether to my own judgment. Dr. Cory and Mr. Stott, Directors of the National Vaccine Establishment, have been kind enough to examine several animals for me and I have their assurance that the vesicles produced by my cultures could not be distinguished from those produced by current lymph in the ordinary working of their station, and it will be recollected that lymph taken from such vesicles has produced in children results in every way similar to those given by current lymph. Moreover, additional proof is afforded by the fact observed in every case where the experiment has been made that animals which have been inoculated with an active culture and have shown the characteristic reaction have proved on subsequent inoculation with vaccine lymph to be immune to the disease.

Sources of fallacy.—With reference to possible sources of fallacy it may be noted that doubt has often been cast upon experimental work on vaccinia carried out in a laboratory where vaccinated animals have been previously kept. Personally I believe that no fallacy is likely to arise from such a cause, and I base my opinion upon the following facts. In my early experiments, for the purpose of putting this question to the test, animals have frequently been inoculated over the greater part of the abdomen with ordinary current vaccine lymph and over a small area with a culture which was known to be sterile. In no single instance have the experimental incisions become contaminated with the vaccine virus. It is therefore, although doubtless within the bounds of possibility, yet at all events excessively unlikely that all, or a large proportion, of similar incisions made under similar circumstances and used for the testing of an active culture should become contaminated. In other cases there have been made over a limited area a number of experimental incisions some of which have been inoculated with an active culture whilst others have remained uninoculated. The rest of the abdomen has been covered with incisions inoculated with ordinary vaccine lymph. In no single instance in which such an experiment has been made were the uninoculated incisions found to show any trace of infection. It is, of course, possible, and indeed perhaps not improbable, that in the hands of a careless experimenter contamination might occur, and it is by no means unlikely that in a long series of experiments some few might be vitiated by untoward circumstances. In any case it appeared desirable to exclude every possibility of error from such a source and consequently, in every instance where an experiment had been carried out under circumstances which seemed to admit of any doubt being cast upon the result from the above or any other cause it has been repeated under conditions admitting of no such doubt and the first result checked. In this way the inoculation experiments have been repeated upon a vaccine-free farm and the results obtained have been quite as successful as those first arrived at.

The specific organism in the tissues of animals inoculated with the cultures.—As soon as it was discovered that inoculation of the pure cultures upon susceptible animals was followed by the development of typical vaccine vesicles, an examination of these vesicles was undertaken with the object of determining in them the presence of the specific organism. For this purpose vesicles as typical as possible were selected and were excised at periods of their development which previous experience had indicated as being most favourable. The pieces of tissue so obtained were hardened sometimes in absolute alcohol and sometimes in a mixture of equal parts of Müller's fluid and a saturated solution of mercuric chloride in a 1 per cent. aqueous solution of acetic acid. They were subsequently sectioned and were stained by the modified Gram's method or by Löffler's methylene blue. It is unnecessary to enter minutely into the appearances observed. Suffice it to say that examination revealed the presence of the diplobacillus, and that in morphological characters, in staining reactions, and in distribution it corresponded closely with similar bacilli observed in the sections of vesicles originally examined which had been produced by ordinary vaccine lymph.

Thus in the organism which I have described as the diplobacillus vaccinia is found a virus which occurs in

Digitized by Google

the vesicles (and tissues surrounding them) of ordinary vaccinia, exhibiting special morphological characters and staining reactions and having a special distribution in the tissues. By special methods which have been indicated pure cultures of this organism may be prepared, and such cultures when used for the inoculation of susceptible animals give rise to vesicles which are described by experts as being indistinguishable from those produced by current vaccine lymph. Moreover the animals which have been so inoculated are found subsequently to give no reaction when revaccinated with active lymph. Finally, sections through the vesicles so produced are found upon examination to contain the organism in large numbers and exhibiting the same morphological characters, staining reactions, and distribution as the organisms originally found in the vesicles of typical vaccinia.

ON THE STRUCTURE OF THE SEMI-LUNAR AND FLAGELLATE BODIES OF MALARIAL FEVER:

AN APPENDIX TO "THE INOCULATION THEORY OF MALARIAL INFECTION."[1]

BY DR. AMICO BIGNAMI,

PHYSICIAN TO THE HOSPITAL OF SANTO SPIRITO, ROME, AND UNIVERSITY LECTURER ON PATHOLOGICAL ANATOMY,

AND

DR. G. BASTIANELLI.

AMONG the objections made by one of us (Bignami) to the hypothesis of Manson one had reference to the significance of the so-called flagellate bodies.[2] The following notes deal chiefly with the structure of the flagellate bodies. These bodies which, as we know, only form after the blood has been withdrawn from the circulation represent, according to Manson, parasites in sporulation the spores of which, "in the interests of the extra-corporeal life of the plasmodium," take on this special form of mobile and flagellated filaments. These forms therefore constitute the first phases of the malarial parasite outside of man. To this view one of us (Bignami) opposed the opinion of Grassi and Feletti, according to whom the flagellates are nothing but the dying forms of the parasite, and also pointed out that no one had hitherto demonstrated in these filaments the structure which ought to be found in spores, more especially the presence in them of chromatin. Subsequently various observers—as Marshall, Ross, and Manson himself—sought to determine experimentally the conditions under which flagellation occurs and they have thus shown the importance of moisture and of exposure to the air as affecting the process, and Manson, by staining preparations of blood containing the semi-lunar and round bodies (which had first been kept for a certain time in a kind of moist chamber and then dried) with a weak solution of carbol-fuchsin, attempted to demonstrate that the mobile filaments exist pre-formed in the interior of the round bodies from which they subsequently emerge.

In spite of these researches which have brought to light some interesting facts it may be affirmed that the structure of the flagellates of *human* malaria had not hitherto been studied by methods which permitted of a minute morphological analysis. Accordingly in the present year in following up our inquiries into the life of the parasite outside the human body we also studied afresh the formation of these bodies.

Regarding the internal structure of the flagellates we do not possess any information that we know of beyond that given by Sacharoff who, describing the structure of flagellates in crows taken from the nest, the blood of which contained innumerable parasites, considers the flagella as chromosomes originating in the nuclei of the body of the parasite and flagellation as a process of perverted karyokinetic division accomplished in a violent manner.

The researches conducted by us during the past summer had for their object the elucidation of the structure of the semilunar bodies, the flagellate bodies originating from these, and the flagellate bodies derived from the large rounded pigmented bodies belonging to the tertian parasite. For this purpose we employed a great many specimens of blood prepared after the method of Romanowsky. The staining was done on cover-glasses on which the blood was spread in the usual way and which were kept in a moist chamber for a length of time varying from ten to twenty minutes or even longer and then rapidly dried and fixed with absolute alcohol. We may say at once that in the majority of the flagellates the flagella or mobile filaments are thus seen to consist essentially of a filament of chromatin which is displayed with great distinctness by the method described. And we may add further that Professor Koch who worked during the summer in the Hospital of Santo Spirito at the subject of malaria succeeded in demonstrating by the same or an analogous method the presence of chromatin in the flagella of the flagellate bodies derived from crescents and showed one of us a specimen in which this was displayed.

The following are the main results of our researches. The flagellates originating from crescents, as well as those from the pigmented bodies of tertian fever, do not all present the same details of structure. Some—and they are not numerous—present the appearance of a protoplasmic body containing in its mass some filaments or blocks of chromatin. From the protoplasmic body project the flagella, generally four in number, made up entirely of a homogeneous substance stained pale blue like the protoplasm. It cannot be objected that in these cases the chromatin fails to be placed in evidence on account of deficient staining, because the chromatin contained in the body of the parasite is stained in the typical way. Other flagellate bodies—and they are more numerous—present a pigmented protoplasmic body of a spheroidal form in which the particles of chromatin have, so to say, emigrated to the periphery. From these peripheral chromosomes issue filaments of chromatin which constitute the principal part of the flagella. The latter in this case also usually number four. Finally there are a few flagellates some flagella of which contain chromatin, while one perhaps consists of nothing but protoplasm.

The structure of these mobile filaments is thus complex. According to our observations they consist of a thread of chromatin substance surrounded by a thin layer of protoplasm prolonged to both extremities. In the rare instances in which one succeeds in finding an isolated filament it would seem as if the chromatin substance tends to occupy the centre, while the two extremities consist of protoplasm. That there exists a continuous peripheral stratum of protoplasm cannot always be made out, but we have reason to think that this is a constant arrangement since even in those filaments which appear to be made up entirely of chromatin it is readily seen that at the points where, perhaps in consequence of the method of preparation, interruptions in the chromatin occur there is a substance faintly stained blue which maintains the continuity of the filament.

As regards the origin of these so-called flagella it can be shown, especially in the flagellates of tertian fever, that they arise from the nucleus. In fact, the large pigmented bodies of tertian fever when the process of flagellation is complete are seen to be divided into two masses. Of these, one mass consists of protoplasm strongly pigmented with granules of melanin; the other is a hyaline sphere with a few granules of black pigment round it from which the flagella issue. This hyaline sphere evidently represents the nucleus which has separated from the protoplasm during the interval in the moist chamber, the chromatin of the nucleus having in its turn emerged from the nuclear membrane to constitute the principal part of the flagella. This is the interpretation which the microscopic appearances seem to us to render most reasonable.

In the preparations made in this way and kept in the moist chamber it can also be clearly seen that all the crescents as well as all the ovoid and rounded bodies derived from them contain chromatin, for the most part in the form of small rods, filaments, and granules. In a former article,[3] in describing the structure of the crescents, we noted that in the greater number of cases their nuclear chromatin was not demonstrable; and, indeed, by the method we used—that of staining with hæmatoxylin and eosin preparations dried and fixed with equal parts of absolute alcohol and ether—it cannot well be seen.

Subsequently to this, Ziemann upheld the view very

Digitized by Google

energetically that the crescents have no chromatin substance, and on this ground he advanced the idea that they are sterile forms. It is not easy to understand how this observer could have arrived at such a conclusion, seeing that he used a method of examination practically identical with that employed by us and which has given exactly contrary results in our hands. Perhaps the reason lies in this—that Ziemann, working with preparations dried immediately after they were taken, failed to see the chromatin, concealed, as it probably was, in the midst of the rods and granules of black pigment surrounding it. On the other hand, in our preparations which were kept in the moist chamber the nucleus of the crescents as also the body itself being swollen up and the rods of pigment separated from one another the chromatin is rendered evident, becomes more or less swollen, and is stained by the method of Romanowsky in a typical way.

We shall not now enter upon a discussion of the significance which these structural characters permit us plausibly to attach to the crescents and mobile filaments.[4] It will be easily understood that those observers who, like Manson, look upon the flagellates as the first phase in the extra-corporeal life of the malarial parasite will find in these new facts fresh argument in support of their opinion. But we hold at the same time that they must not be considered as necessarily irreconcilable with Bignami's own hypothesis as to the significance of the semilunar bodies, especially when that hypothesis is studied in the more complete form in which it is presented in the last article written by us upon this subject.

Bignami's first hypothesis has been misunderstood by many, as Thayer and Hewetson justly observe.[5] We have indeed favoured the idea that the semilunar bodies are sterile on the grounds that one never sees in them any form of multiplication and that they have no relation to relapses; and these assertions, even in the light of these new observations, we still hold by as in accordance with the truth. In other words, we contended that the crescents are sterile bodies *in man* and *as far as man is concerned*. In fact, we put forward the additional hypothesis[6] that these bodies represent those phases of the life of the malarial parasite which in other parasites are continued and completed outside of the host. Should such migration from the host fail to occur, then that phase of life which cannot be completed except in the outside world or in a new host will be carried out in an abortive way and will terminate in forms of degeneration.

Certainly these new researches render probable the hypothesis that the cycle commenced in the blood of man is completed in some species of mosquito,[7] but they nevertheless do not negative the truth of the fact alluded to in our first hypothesis in those cases where the passage from man to the new host fails to take place.

Rome.

[4] A complete account of the results of these researches, not only in regard to crescents and flagellates but also to the structure in general of malarial parasites, will shortly be published in the Bullettino della Reale Accademia Medica di Roma.

[5] W. S. Thayer and J. Hewetson: The Malarial Fevers of Baltimore. The Johns Hopkins Hospital Reports, 1895, p. 215.

[6] Loc. cit., p. 37 of the extract, et seq.

[7] Since the above was written we, along with Grassi, have succeeded in demonstrating that the semilunar bodies do actually develop in the middle intestine of a mosquito (Anopheles claviger). It is probable that this is the same species as Ross's "dappled-winged" mosquito, in two of which he observed a similar development. These facts allow us to accept the above inferences with less reserve.

OPENING OF VICTORIA HOSPITAL, KINGSTON-ON-THAMES.—On Monday, Dec. 12th, the Duke of Cambridge opened the Victoria Hospital, Kingston-on-Thames, erected by the inhabitants as a memorial of the Queen's long reign. The site for the new building was presented by his Royal Highness. The freedom of the borough was conferred upon his Royal Highness who was subsequently entertained by the mayor at luncheon.

DIPHTHERIA IN SWANSEA.—The epidemic of diphtheria shows no signs of diminution and is exciting considerable anxiety in the town. Last week 37 cases were reported, against 39 in the previous week. The *Herald of Wales* complains that the medical officer of health, Mr. Ebenezer Davies, has directed that no particulars as to cases of disease notified shall be given to the press on the ground that notifications are private information.

ON THE ADMINISTRATION OF A CERTAIN MIXTURE OF CHLOROFORM AND ETHER IN GYNÆCOLOGICAL OPERATIONS BY MEANS OF A CLOVER'S INHALER WITHOUT THE BAG.[1]

BY W. J. McCARDIE, B.A., M.B., B.C. CANTAB.,
ANÆSTHETIST TO THE GENERAL HOSPITAL AND TO THE DENTAL HOSPITAL, BIRMINGHAM.

IN view of the great increase of the records of death during the administration of anæsthetics, methods and statistics, especially when obtained from large numbers of cases and classes of patients, have exceedingly great value, and I propose, with ap logies for some reiteration in what follows, to give the results partly of my own experience and partly of the experience of others in regard to a particular anæsthetic mixture and the special method of using it. Mixtures containing chloroform and ether, although viewed with disfavour by many administrators as be'ng neither the one thing nor the other, have certain undeniable advantages, more especially when they contain ether in an effective proportion. In the German statistics now to be quoted the fact that the mixture shows a smaller death-rate than either ether or chloroform given separately points, in my mind, to the inference among others that an efficient quantity of ether had been added to the chloroform. Before describing and considering the method mentioned at the head of this paper I will first touch on several points in connexion with anæsthetic mixtures containing ether and chloroform.

German statistics of anæsthetics from 1890 to 1897, collected from scores of thousands of cases, give the death-rate in the following proportions according to Haenkel[2]: chloroform, 1 in 2039; ether, 1 in 5090; ether + chloroform, 1 in 7594. The Austrian mixture of ether one part, chloroform three parts, and alcohol one part is not included in the above statistics, for it contains only a small and probably ineffective proportion of ether.

Statistics of fatalities during the administration of anæsthetics notoriously vary greatly, and though the figures given may not be absolutely correct, yet if all unrecorded cases were published and added to the above figures I believe that probably the number of deaths would be found to be double those indicated by the above figures. In any case probably the proportion of deaths under chloroform to those under ether and the mixture is about right, and we may conclude that a mixture of ether and chloroform in which a sufficient quantity of ether is included forms probably the safest anæsthetic in common use for ordinary surgical work, for on the one hand the very real after-perils of ether are much diminished and the present dangers of chloroform are by its dilution and the addition of the stimulating ether in great measure obviated. It will be said that the administration of ether in suitable cases by men accustomed to its use has practically very little of danger and no doubt to a very large extent this is so, but much practice is needed to give ether with any great degree of comparative perfection and in such a way as to minimise the possible and real danger of after-bronchitis and pneumonia, more especially in abdominal cases. We therefore have not to consider the administration of anæsthetics by the specialist but as forming a part of the everyday work of the surgeon, house surgeon, or practitioner. Statistics of the Germans and practical experience go far to show that a mixture in all cases freshly prepared, such as the A.C.E. or a mixture containing ether and chloroform in which the ether is present in rather greater proportion than in the A.C.E. mixture—say in the proportion of 2 to 1 or 2½ to 1—is reasonably safe and probably the safest anæsthetic for routine use. Several cogent reasons are: (1) both ether and chloroform are diluted; (2) are given with plenty of air; (3) there is less chilling and irritation of the air-passages than when ether is given alone; (4) the breathing is more obvious than when chloroform alone is given; (5) the pulse and respiration are rather stimulated than depressed; and (6) the

[1] A paper read before the Birmingham Branch of the British Medical Association on Nov. 10th, 1898.

[2] Handbuch der Inhalations-Anästhetica, second edition, p. 61.

Digitized by Google

dangers of over-depression by chloroform or of over-stimulation by ether, the latter being a factor not always realised by the administrator, are to a certain and sometimes large extent avoided. We should strive as far as possible so to proportion the quantities of ether and chloroform in a mixture that the depressing effect of the chloroform (which is so markedly shown by the fall in blood-pressure) will be wholly or almost wholly counteracted by a proper amount of ether; indeed, it would be safer for the patient that there should be in the mixture a little more ether than would be sufficient to neutralise the general depressant effect of the chloroform—just enough, in fact, to slightly increase the fulness, strength, and rapidity of the pulse and the number and depth of the respirations and perhaps to make the breathing a little mucous in character. Thus the effect of the shock during operation will be lessened.

An advantage (first pointed out by Schleich of Berlin but not yet properly appreciated) of certain mixtures of about the above strength is that their boiling point—that is, point of maximum evaporation—more nearly approximates the temperature of the body than does the boiling point of ether or chloroform alone. Ether, e.g., boils at about from 34° to 35° C. and chloroform at about from 60° to 62° C., while the boiling point of the A.C.E. mixture is about 48° C. It is to be noted that the boiling point of ether prepared from methylated spirit is lower than that of ether prepared from rectified spirit, and if the former be used in such mixtures the resultant more nearly has its point of maximum evaporation at the body temperature than if the rectified ether be used. I can in practice detect very little difference, during administration or after it, between the two preparations of ether and nearly always use that prepared from methylated spirit. Practically, then, to a large extent the advantages of both ether and chloroform can be combined and the disadvantages mitigated by giving ether and chloroform in the proportion of 2 or 2½ or 3 parts of ether to 1 part of chloroform. If such a mixture be given openly in the case of children or by a Silk's celluloid or metal inhaler to adults one can, of course, increase the proportion of either constituent at will and conveniently.

I now give a description and a few statistics of a method of administering a certain mixture of chloroform and ether which is, so far as I know, nowhere else practised than in the Midlands, though here it has been in use for more than fifteen years and almost exclusively by gynæcologists, Mr. Lawson Tait being, I believe, its originator. This mixture is the routine anæsthetic here in Birmingham for most operations performed by the majority of gynæcological surgeons. The lengthened satisfactory experience of many operators, confirmed by favourable statistics which comprise thousands of cases, justifies to a large extent the great confidence reposed in the mixture and in its system of administration. The method to which I wish especially to draw attention consists briefly in the use of a mixture of ether and chloroform in the proportion of 2 parts of ether to 1 of chloroform by volume administered by means of a Clover's portable regulating inhaler without the rubber bag. The ether generally used in the mixture is the methylated variety, and of specific gravity of 0·720, while by some administrators rectified and by others methylated chloroform forms the other ingredient. I will first give the statistics:—

Hospital ...	4431	operations to the end of July, 1898, with	2 deaths.
Private (about)	9750	" " " "	1 death.
Total ...	14,181		3 deaths.

To show the proportion of operations performed in the Birmingham and Midland Hospital for Women under the influence of this mixture I looked through the record of operations for several months, and among them the month of May, 1898, and found that there were 32 operations for which the anæsthetics respectively were: In 27 the mixture of ether two parts and chloroform one part; in 2 chloroform; in 1 chloroform followed by the mixture; in 1 the mixture with the addition of more chloroform; and in 1 no anæsthetic. Thus the percentage of cases in which the mixture was used was 87·5. Again, taking other months at random for the sake of illustration, in another shorter month of this year 26 operations were all performed under the influence of this mixture = 100 per cent. In January, 1887, there were 22 operations, in every one of which this anæsthetic was used. In January, 1898, there were 32 operations in 30 of which this anæsthetic was used = 93·75 per cent. In July, 1898, there were 26 operations, in 25 of which the anæsthetic was used = 96 per cent. Thus on an average more than 90 per cent., really about 95 per cent., of the operations in the Birmingham and Midland Hospital for Women (and I believe the same assertion may be made regarding the operations in the Wolverhampton and District Hospital for Women) have of late years been performed under the influence of this mixture given by the method described, and nearly all the operations done in private by the staff of the above-mentioned hospitals have in recent years also been performed under its influence.

These statistics have especial value because they apply only to patients of the female sex and in perhaps 99 cases or more out of every 100 to adult women. Gynæcological operations are, taking them as a whole, longer and more severe in their nature than the usual run of general surgical procedures and as so many cases complicated by abdominal distension or pregnancy have to be dealt with and often at length the dangers of anæsthetisation are rather greater in proportion than those incurred in general surgery. As regards the deaths which have taken place during the administration of this anæsthetic one occurred in a patient who was extremely ill from chronic double pleurisy of an extensive nature and who also had an enormous ovarian tumour pressing upwards and embarrassing the heart and lungs. Operation was urgent in this instance. In another case, also the subject of a huge ovarian tumour which practically when the patient was in a horizontal position allowed very little movement to the heart or lungs, death occurred. Both of these cases would in all probability have ended fatally whatever anæsthetic had been used and operation was the only chance of life, for the patients were *in extremis*. In the third case[3] the mixture was administered to a very healthy middle-aged woman, nothing being found on physical examination to contraindicate an anæsthetic. Before she was fully anæsthetised, the patient suddenly became rigid, blue and pulseless and the breathing spasmodic, and death ensued in spite of the usual means for resuscitation. It was evident that for at least ten minutes after cardiac movements had completely ceased she was making efforts to breathe. About 3 drachms of the mixture had been used. At the necropsy no particular abnormality was noted except congestion of the brain. Death seems to have occurred from syncope. One of the deaths occurred in private and 2 in hospital practice. If we omit the first 2 fatal cases which would have so ended in any case it will be seen that practically there was only 1 death directly due to the anæsthetic in over 14,000 cases—a statement which I think could rarely be applied to the administration of chloroform alone by whomsoever and however given, and seldom to a similar number of ether administrations and which points to the comparative safety of this anæsthetic in the class of cases in which it has been used. About 50 per cent. of the operations have been laparotomies and speaking generally I think, as I said before, that gynæcological operations are in their nature at least as severe as, if not more severe than, the ordinary run of surgical procedures.

The boiling point or point of maximum evaporation of the mixture of two parts of the methylated ether and one part of the purest rectified chloroform is about 102° F., which is practically = 39° C. or a temperature slightly above that of the body. The advantage of such a boiling point has before been alluded to. Chloroform and ether forming together but a mechanical mixture, not a chemical compound, it might be thought that ether would come off more rapidly and leave in the end pure chloroform to be inhaled to the detriment of the patient and discomfiture of the administrator; but for the practical purpose of inhalation this difficulty does not occur, for so far as can be judged in practice by the smell of the mixture and the pulse and respiration of the patient there is no difference ascribable to the anæsthetic between the condition of the patient at the beginning and at the end of a dose poured into the receiver of the Clover's inhaler. As Dr. Hewitt in his book on "Anæsthetics" remarks of the A.C.E. mixture so in this case, "the ether present in the mixture certainly does not show that inclination to rapid escape which it has been supposed to possess." Probably because ether mixes freely with chloroform and alcohol it does not evaporate quite so rapidly as if given by itself, being held back by the chloroform and alcohol.

Practical points in administration.—1. The mixture must be freshly prepared, and so far as I can judge the pure

[3] Death under Mr. Lawson Tait's Anæsthetic Mixture: THE LANCET, July 14th, 1894.

Digitized by Google

methylated ether may be used with as good results as the rectified preparation. 2. The quantity is to be measured and used in exactly the same way as pure ether, except of course that the bag is not utilised and that the face-piece is not removed for air supply. 3. The body of the inhaler should be previously warmed unless the room be hot or the patient weak. 4. The face-piece must fit accurately and be kept in exact apposition to the face during the whole of the anæsthesia. 5. During induction of narcosis the indicator must be moved on much more rapidly than if ether were being given until it reaches "full," and be kept there till anæsthesia occurs. 6. When this happens the indicator in many cases can be brought back to "3," or even to "2," and kept there throughout narcosis. In some cases it has to be kept at "full," and in others even thus the patient cannot be kept fully anæsthetised unless artificial heat—e.g., a hot towel—be applied to the body of the inhaler to increase evaporation. The anæsthesia obtained is very like that following the use of the A.C.E. mixture, the pulse and respiration being stronger and more rapid than in the case of chloroform narcosis, and the colour as a rule is excellent throughout.

Advantages of the mixture.—1. It is very pleasant to the smell and taste and non-irritating to inhale in ordinary doses. 2. Induction of anæsthesia, in women at any rate, is rarely accompanied by excitement, rigidity, or struggling. The mixture compares favourably in these respects with the A.C.E. mixture, and whether the absence of those untoward symptoms is solely due to the absence of alcohol or is owing to this fact acting together with another—viz., that the musculature of women is generally weaker and far less used than that of men, is doubtful to my mind. 3. A quiet anæsthesia is obtained, very suitable for most operations, including laparotomies and perineal procedures, for there is no rapid heaving abdominal respiration as is the case with ether, and yet there is a distinctly stimulating effect as compared with chloroform. 4. In my experience patients suffering from most forms of heart trouble or from slight respiratory lesions, or even from bronchitis of moderate degree, take the mixture very well. Indeed, in most cases in which ether or the A.C.E. mixture is generally given this mixture acts admirably. I personally see no objection to its use in marked cases of renal disease. 5. After-effects of any kind are very rare, and I really cannot hear of any serious or even comparatively severe sequelæ attributable to administration; even if these happen in slight degree they are neither as persistent as those following the use of chloroform nor as troublesome as those after ether, considering that after-effects of serious character, especially in the form of respiratory troubles, are more likely to follow laparotomies than other operations and that about 50 per cent. of the cases quoted were operations of this nature, it is an important advantage to be able to predicate this point. 6. Owing to the fact that comparatively little chloroform is used noxious fumes of carbonyl chloride and hydrochloric acid are not so abundantly given off as when chloroform alone is given—say in a small, badly ventilated, and gas-lighted room. Again, there is less danger of ether vapour from the mixture catching fire in the presence of a fire or light than if it were being administered in the pure state.

Advantages of the method.—1. It is more convenient than any other way of giving the mixture; the apparatus can be managed with one hand and it needs very seldom to be removed for replenishment. 2. The quantity of the anæsthetic given can be accurately graduated and kept constant and is strictly limited to a certain moderate amount in the majority of cases; these I regard as most important points. 3. The utmost limit of quantity is in most cases little above that needed to maintain anæsthesia—i.e., the safety point can be only in small degree exceeded—and in very many instances that limit is practically the full quantity necessary for the purpose of anæsthetisation or even slightly below it, so that heat has to be applied to the apparatus to increase the rate of evaporation. 4. Thus it is generally difficult to give too much or a sudden overdose of the anæsthetic, and supposing that the operator has an inexperienced administrator or is operating without skilled assistance he can well induce anæsthesia himself and, putting the indicator to, say, "3," tell the anæsthetist or attendant to keep it there. If imperfect narcosis happens one can tell him to put the indicator at "full." 5. Anæsthesia is as easily and rather more quickly produced than by giving the A.C.E. mixture in the ordinary way—viz., by means of a Skinner's mask and Silk's inhaler.

Disadvantages of the mixture.—These are as a rule very few and slight in practice, as the difference in rate of evaporation of chloroform and ether does not seem to come into play to any extent. In very marked bronchitis or other pulmonary affection or in very old people or very marked cases of abdominal disease—e.g., large ovarian tumours or cases complicated by abdominal distension—the mixture is as safe as the A.C.E. mixture. Mild bronchitis is the chief sequela and is rare. I have not heard of pneumonia as a sequela. This lesion, on the other hand, is comparatively frequent after long laparotomies performed under the influence of ether. In a very few cases, especially in alcoholics, anæsthesia is imperfect and one must either increase the proportion of chloroform or adopt some other anæsthetic.

Disadvantages of the method.—These are likewise few. 1. In a cold room or with very strong or rather alcoholic women one has sometimes to warm the reservoir before use or afterwards to apply a hot towel to it. 2. It is not much good for strong or alcoholic men. I have not used it at all for children. There is no apparent danger in breathing the mixture, into which chloroform enters so largely, through the comparatively narrow air channels of a Clover's apparatus; as elsewhere remarked, the bag is even as a routine practice used by one skilled administrator until full anæsthesia has been induced, thus for a few minutes cutting off the air-supply altogether. Such a proceeding is the result of experience, not of following strictly the ordinary canons of anæsthetisation. The conditions generally held to contraindicate the use of the mixture are those in which by the majority of practitioners the administration of ether is contraindicated. This tends to show indirectly the distinct influence and efficacy of the proportion of ether present. Briefly, the mixture is not given in cases of marked pulmonary or renal disease or to old people or children. In all these conditions chloroform is to be preferred. Ether is practically never used by those who incline to this method of anæsthetisation, chloroform being the alternative anæsthetic. As during the administration of all anæsthetics untoward events may and do occur, so with this mixture. There have been times when there has been great anxiety for the patient, when artificial respiration and other means of resuscitation have had to be resorted to, and when another anæsthetic has had to be substituted for the mixture, but so far as I can learn causes for uneasiness do not arise so frequently as during the ordinary administration of ether or chloroform alone, and the general opinion of the surgeons who operate during narcosis produced by this method is most favourable—indeed, they have more confidence in it than in any other anæsthetic and their experience, individual and collective, of other agents as well as of this mixture has been large.

Mr. Lawson Tait's large experience of chloroform, ether, bichloride of methylene, and this mixture induced him to write to me as follows: "Then [i.e., about the year 1882] we found a mixture do well—2 ether and 1 chloroform—and that I believe is the best of all anæsthetics, save in old age and damaged kidneys, for all kinds of work. I think if introduced by nitrous oxide it would be an ideal anæsthetic." The opinion and experience of the many other gynæcologists in the Midlands who use the mixture coincides with that of Mr. Lawson Tait. Personally I have used the mixture in a good many cases of operations on women and very occasionally have administered it to men, and have formed a high opinion of its merits for gynæcological operations as given by the method described. In only one case, that of a very alcoholic woman, have I not been successful in inducing anæsthesia, but was obliged to resort to chloroform. Its chief demerit is to my mind the trouble of applying heat to the apparatus if the room be cold or the patient strong or rather alcoholic. One skilled administrator often uses the bag until the patient is anæsthetised, affirming the safety and humanity of rapid induction of anæsthesia. Equal parts of chloroform and ether have been given by this method and more than once, I believe, even pure chloroform, without untoward result. Finally, the procedure described seems to fulfil its object admirably in a certain class of patients—viz., women subjected to more or less the same kind of operation (i.e., abdominal or gynæcological)—and that much-to-be-desired end, that of making it difficult to give too much of the anæsthetic, is in many cases partially and in some cases wholly attained without the use of novel or cumbrous apparatus or the adoption of inhalers which require constant watching and draw the attention of the administrator from the condition of the patient.

I must now express my indebtedness and thanks to Mr. Lawson Tait, Dr. Thomas Savage, Dr. A. E. Clark, Mr. J. W. Taylor, Mr. Christopher Martin, Mr. J. Furneaux Jordan,

Dr. Frederick Edge, and to the committee of the Birmingham and Midland Hospital for Women for kindly allowing me to make use of their records in order to compile the statistics and also for giving me much information on the subject of this article.

Birmingham.

ON THE PREVENTION AND CORRECTION OF SHORT LEG IN HIP DISEASE.

BY ROBERT JONES, F.R.C.S. EDIN.,
HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

No matter what care may be taken in the early treatment of hip-disease a certain amount of subsequent deformity seems inseparable from a large number of the cases. The percentage is variously stated by different authors at between 70 and 80. Doubtless certain factors tend to lessen this estimate, prominently amongst which may be placed an early diagnosis and treatment and the efficient mechanical control of the limb. I am obliged to admit that in my own practice until lately in a proportion of cases (certainly a small one) even where a patient has been presented to me without appreciable deformity I have been powerless to prevent

FIG. 1.

A. B., aged twenty four years. Practical shortening 4 in.

shortening. That my experience is not unique is proved by the literature of the subject and by the continued efforts made by surgeons at home and abroad to devise methods for the prevention of short leg. Of one thing we may rest assured that however effectually we may by mechanical means modify deformity in active arthritis much more radical measures are required where the joint is sound but ankylosis and deformity remain. It is with the view of endeavouring to simplify the methods of preventing adduction and to facilitate its correction once it has occurred that I submit this statement for consideration. The deformities which constitute short leg comprise all or most of the following conditions—viz.: flexion, adduction, internal rotation, tilting of pelvis, and arrest of growth. The first four of these conditions—viz., flexion, adduction, internal rotation, and tilting of pelvis—I venture to think may in the future be

FIG. 2.

Same case as Fig. 1. After transtrochanteric osteotomy. No practical shortening.

avoided where we have an early case to deal with. Obviously we can only modify the shortening caused by arrest of growth by deflecting the pelvis sufficiently to ensure apparent equality of the limbs. Without entering into a discussion as

FIG. 3.

A boy, aged ten years. 4 in. practical shortening.

to the causes of short leg I would state that, contrary to the teaching of surgeons, it often occurs without the complication

Digitized by Google

of abscess, that it often occurs very suddenly, and that in quite a number of cases it happens in robust children and is absent in the weakly and emaciated. I would further add that though abduction is usual in the so-called first stage of hip disease I have frequently noted in cases with what may be called a strongly deforming tendency that adduction

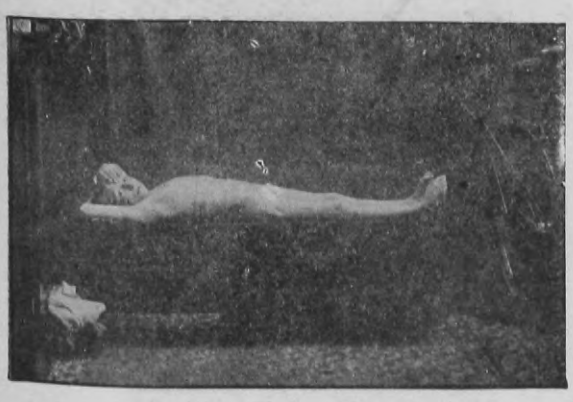

FIG. 4

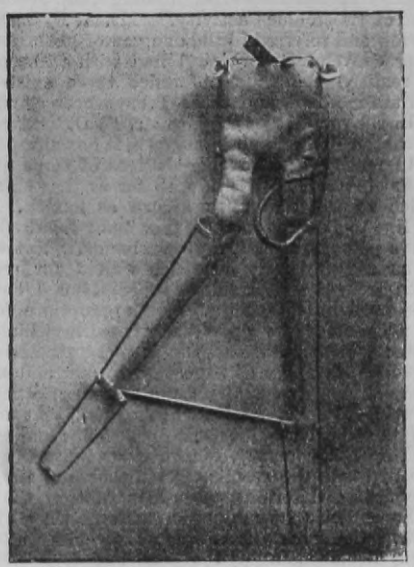
Same case as Fig. 3. After osteotomy and abduction. Pelvis has been lowered on diseased side and shortening obliterated.

is present almost from the first and that abduction has not once been noted in the so-called first stage. Again, it must be recollected that adduction may occur without tilting of the pelvis and without displacement of the femoral head. In proof of the fact that body weight is not the all-

FIG. 5.



Same case as Figs. 3 and 4. Shows the apparent lengthening by pelvic depression of leg which was 4 in. short.

important factor in the production of deformity, as many authors would have us believe, one has only to adduce the fact that the whole series of elements which make for short leg may appear while the patient is lying in bed.

The best routine appliance for hip disease is undoubtedly the Thomas splint and I always use it in those cases where it is sufficiently effective to control deformity. For this purpose the abduction body wing should generally be employed and the not easily or generally acquired art of its application should be thoroughly mastered. In some cases, however,

FIG. 6.

Abduction splint.

where the structures about the joint seem to thicken early and glide backwards I am using a special abduction splint (Figs. 6 and 7). The new splint is so designed as to keep the diseased limb fixed in an abducted position and it effectively prevents any elevation of the anterior superior spine on the sound side; it governs rotation, flexion, and abduction

FIG. 7.

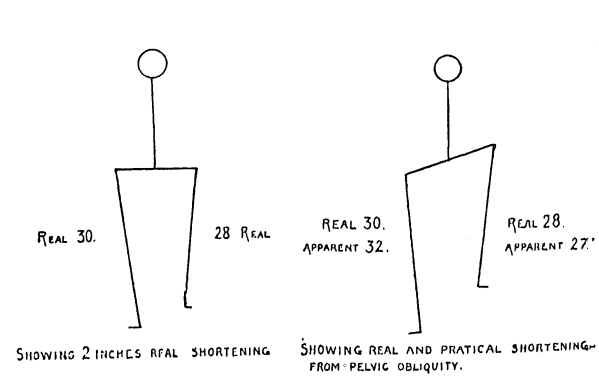
Abduction splint applied.

and in my belief solves the problem of the prevention of short leg, for by its help I can with confidence predict in every early case that recovery will take place without shortening provided we have not to deal with arrested growth. The importance of this assurance will be appreciated when we note that while shortening occurs in, say, 70 per cent. of the cases arrest of growth in any but a barely recognisable extent

Digitized by Google

occurs in not quite 15 per cent. This arrest I find is usually not confined to the femur but is shared by the other bones of the limb.

In a discussion held lately at the Clinical Society of London, at which I was present, Mr. Watson Cheyne, in order to emphasise an argument, stated that "no one would ever think of immediately straightening a hip or knee during any stage of tuberculous activity." Mr. A. E. Barker took a similar view and referred to the dangers of general infection. In a later conversation which I had with these gentlemen I fully realised the wide difference there exists between metropolitan methods and those I have been accustomed to follow. In the practice of the late Mr. H. O. Thomas, in that of Mr. Rushton Parker, and in my own, it has always been the custom to rectify with varying degrees of force any tuberculous joint in a wrong position, so far as that phrase might be applied to the deformity known as flexion. I should scarcely like to attempt to guess how many hundreds of such cases have passed through my own hands. Not only have I never as a preliminary condition waited for recovery to take place from the tuberculous process, but I have looked upon the active stage as that most appropriate for reduction on account of the great facility with which it may be effected. In the case of the knee particularly I commonly reduce an angle of from 30° to 40° and allow the patient to travel home the same morning, sometimes a considerable distance. I am not aware that my statistics are in the least harmed by such seemingly rude methods; on the contrary, I have every reason to be more than satisfied with the results. In the case of the hip even extensive flexion deformity does not shorten the limb to nearly the extent that adduction with pelvic tilting does, and I have for some time directed my chief attention to preventing displacement of the head and to keeping under control the level of the right and left anterior pelvic spines. My practice now in all cases of displacement of the head is to endeavour to at once reduce shortening by force sufficient to effect this purpose. If this be attempted while disease is active and before ankylosis, either fibrous or bony, has had time to take place scarcely any difficulty is experienced and pulleys have rarely to be used. This, of course, refers to the case of children. The force that governs the displacement generally suffices to rectify pelvic obliquity, while the flexion can be overcome at the same time by ordinary methods. If the case be of long standing and the structures around the hip-joint are much thickened two or three applications of the pulley may be required at intervals of about a week. In cases where the tuberculous process has subsided and ankylosis remains certain further procedures are necessary and will be described later. Having restored as far as possible the displacement of the hip and the length of the limbs the patient is placed in the new abduction apparatus, where, as I have stated, the parts are so combined as to effectively prevent the slightest tilting of the pelvis in any but in the direction of advantage to the diseased side. The patient is maintained in this apparatus until the phase of disease productive of deformity has passed. When the disease admits of it he may be transferred to an ordinary walking splint, the abducted limb meanwhile being brought into its proper position, but practically during the whole of treatment he should live in the open air. I am quite convinced from my own practical experience that this abduction splint is an effective preventive of adduction, but if further argument were needed it is supplied by the fact that without recourse to force one can by its use gradually overcome any moderate amount of shortening which may be found to have occurred in a recent case. If it can correct deformity it can much more easily prevent it.

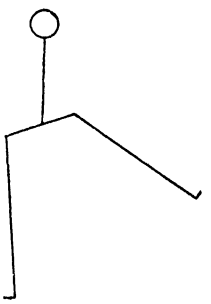


I would now deal with another important class of cases. I allude to those cured of their hip disease, some of whom are children and some adults, and who may have shortening varying from 2 in. to 6 in. or 7 in. due to femoral displacement and oblique pelvis. I have operated already upon about 50 such cases and can speak most hopefully of the results. And here it may be well to mention that if we are to keep anything like an accurate record of these deformities we should employ a simple method of measurement for fixing the degree of adduction and estimating practical and real shortening. (Diagrams A and B.) Osteotomy, as we know, has been practised for years to overcome the deformity of flexion. Rhea Barton performed it in 1826 and he was soon followed by Clemmot, Rodder, Maisonneuve, and others. Adams first performed the operation subcutaneously by dividing the neck of the femur. The other operators worked lower down but only Gant divided below the lesser trochanter. Probably Gant's operation is the most popular to-day, but personally I prefer that of Adams if we only have to deal with the deformity of flexion. Although something must be said in favour of a section which cannot be interfered with by a shortened psoas and iliacus, yet I have found that in cases of right-angled deformity of the hip the upper part of the femur left fixed after Gant's incision has an ugly way of encroaching upon Scarpa's triangle. Of this I am also certain, that even if an osteotomy incision be made through inflamed tissue, as must sometimes occur in Adams's operation, union is not in the least hampered. Personally, with a view of not merely rectifying a flexion angle which has been the general object of a femoral osteotomy but with the intention of lessening or obliterating adduction with pelvic tilting, I make my incision obliquely through the great trochanter (Diagram F). This often involves hard work because of the thickness and the sclerosed condition of

FIG. 8.

Modification of Adams's saw.

the bone. The work is much facilitated by having a small knob on the end of the saw, such as one which Weiss has made for me (Fig. 8). One can saw with much more energy when there is no danger of either transfixion or of losing one's place. It is better where practicable to saw completely through the bone rather than a certain distance and I prefer going through the trochanter because of extra callous exudation, as an ununited fracture will frustrate the object of the operation. The adductors are next subcutaneously divided and in the case of a youth or adult traction is applied by means of pulleys. Very often an inch or an inch and a half may be



gained by this traction (Diagram F) and in this way some of the shortening of actual displacement may be combated. The leg, still fully extended, is placed in a position of abduction (Diagrams C and G), which varies with the degree of pelvic tilting. The greater the tilting the greater should be the abduction. The pelvis on the sound side is fixed and the abduction splint is applied and extension and abduction are maintained (Fig. 7). Seven or eight weeks are allowed to elapse—until, in fact, bony union is completed with the limb in abduction and at an angle with the body.

It is now to be noted that the length of the limbs may be equalised in one of two ways or by a combination of both

Digitized by Google

ways—either by lessening the practical length of the sound limb or increasing that of the short one. By osteotomy and extension the leg is actually lengthened (Diagram E), and by the osseous union of the femur in abduction with the pelvis the elevation of the pelvis on the opposite side is

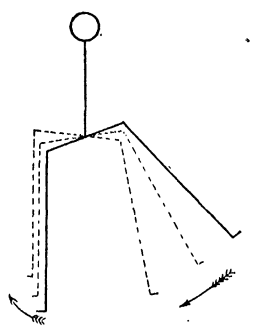


DIAGRAM C

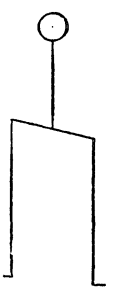
POSITION OF LEG AFTER TRANS TROCHANTERIC OSTEOTOMY.



effected. With an outstretched thigh in one piece with the trunk it is clear that the limb can only be adducted at the cost of elevating the pelvis on the sound side, and in this way several inches of shortening may be remedied (Diagram D).

DIAGRAM D

SHOWING ELEVATION OF PELVIS ON SOUND SIDE BY BRINGING ABDUCTED LEG INTO POSITION.

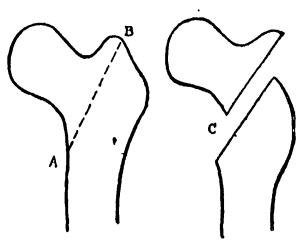


DIAGRAM E.

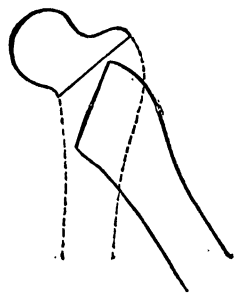
SHOWING FINAL RESULT WITH ADDUCTION OF LEG AND ELEVATION OF PELVIS OF SOUND SIDE

A more difficult class of case to deal with is that where short and firm fibrous union obtains. In such cases I am accustomed to divide the adductors and extend and forcibly abduct and if attempt at lateral movement threatens fracture I perform an osteotomy as if for bony ankylosis; indeed, it is better in such cases to proceed forthwith with osteotomy

DIAGRAM F.



A.B. LINE OF SECTION THROUGH TROCHANTER.

C. LENGTHENING AFTER TRACTION.

rather than complicate the issue by forcing the fibrous bands. Such cases require to be kept much longer in a splint than do those where the fixation is bony and in two or three instances, from a want of experience in this matter, the early removal of restraint has resulted in some return of deformity. It might be supposed that this fibrous union would still allow the adductors to act, no matter how long the restraint and stretching, but this is not so provided sufficient abduction is obtained to counteract any subsequent slight fibrous contraction. If the limb be abducted for a sufficient length of time further contraction is not likely to occur and this accords with what may be assumed to be a surgical axiom that a deformed limb due to arthritis retains the same degree of movement after correction as it possessed before and that if ankylosed at the moment of rectification it is equally ankylosed when reduction is completed. When the splint has been removed the patient should be confined to

DIAGRAM G.

POSITION OF FRAGMENTS WHEN LIMB IS ABDUCTED.

bed for some time until the abducted limb is gradually brought into position and exercises should be prescribed designed to elevate the pelvis on the sound side and depress it on the diseased side. These exercises are very necessary adjuncts and in the case of adults especially because they materially improve the character of the walk.

I do not now enter into the question of pseudo-arthrosis except to state that its results in my hands are most uncertain and that by its attainment the rectification of deformity is not at all complete. I now almost exclusively employ it for the relief of double ankylosis. Of the 50 cases of bony ankylosis upon which I have operated by the trans-trochanteric osteotomy with abduction I will merely briefly state that in most of the cases the practical shortening has been obliterated and that in the rest it has been lessened almost to the point of disappearance. Suppuration has not occurred nor have there been any symptoms of gravity. The pain, which in my earlier cases was marked, can be avoided by a careful adjustment of the groin strap. In 2 cases tuberculous abscess has presented itself, but in both the operation was performed and the disease recovered from. The general health, as evidenced notably by sleep and appetite, has been well maintained.

In conclusion, for the prevention of short leg I suggest: (1) that abduction of the diseased limb should be maintained; (2) that the apparatus to attain this should also govern flexion and adverse pelvic tilting; (3) that where arrest of growth threatens pelvic obliquity should be summoned to assist; and (4) that where displacement of the head has occufred immediate reduction should be attempted. For the correction of short leg with bony ankylosis I suggest: (1) that oblique transtrochanteric osteotomy should be performed; (2) that the adductors should be subcutaneously divided; (3) that the limb should be placed in the position of abduction and extension and kept there until firm union occurs; (4) that after union the splint should be removed and the limb allowed to slowly leave the abducted position; (5) that exercises should be systematically performed in order to depress the pelvis towards the affected side; (6) that in case of fibrous ankylosis where no osteotomy has been performed in order to avoid recurrence the abduction should be maintained for considerably longer; and (7) that this treatment should as much as possible be carried out in the open air.

Liverpool.

BORIC ACID IN MILK.—At the Pontypridd Police-court on Dec. 7th a milk vendor was ordered to pay £1 1s. 6d. for selling milk which the public analyst stated contained 13½ grains of boric acid to the gallon.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ASTHMA DUE APPARENTLY TO ARTERIAL SPASM.

BY JOHN C. THOROWGOOD, M.D., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO THE VICTORIA PARK HOSPITAL FOR DISEASES OF THE CHEST.

THE commonly accepted belief that spasmodic asthma is due to a contraction of those muscles which encircle the smaller bronchial tubes is undoubtedly correct in the majority of cases. It appears to me, however, that there are some cases where the real essence of the seizure lies in a spasmodic contraction of the blood-vessels rather than of the bronchial muscles. If this be so we can readily understand how it is that many competent observers, such as Hyde Salter and Trousseau, have likened an attack of asthma to an epileptic seizure.

Early in 1897 a young married woman was sent to me by Mr. Nichol Cox of Galloway. In her case I believed arterial spasm had much to do with causing the very severe fits of dyspnœa which from time to time assailed her. The patient was of spare build and of nervous temperament and for some years she had been subject to seizures of asthma. She had a quick pulse, weak cardiac sounds, and prolonged expiration, but very little true wheezing sound was heard in the lungs. She told me that all cigarettes and fuming inhalations made her worse. Shortly after her visit to me I saw her in a very severe paroxysm of asthma. Her appearance then reminded me much of that of a person suffering from angina pectoris. Her pulse was 120 and small, and her chest movements were up and down with no true expansion. The wheezing sounds were not so marked as one would have expected from her appearance. The intense pallor and anxious face of the patient made me think of arterial spasm, and the remedy which ought to succeed in such a case should be one which would dilate the vessels. Drop doses of liquor trinitrini did good, but they did not seem to me so efficacious as repeated doses of chloral hydrate (10 gr.). Under this last medicine the relief was unmistakeable and when I called the next day all the asthma was gone and the patient to all appearance had become well. Two months later I heard that she had been to Aix-les-Bains and had returned with a gain of flesh and much general benefit.

This case may not seem a very extraordinary one, for there is plenty of evidence to show the value of chloral hydrate in relieving spasmodic asthma. It is worth while, however, to consider how far arterial spasm may be concerned in the production of some forms of sudden dyspnœa. The failure of ordinary fuming inhalations to give any relief was a prominent feature in this case, while vaso-dilator medicines acted speedily in relaxing the spasm. Dr. Lauder Brunton has recorded an interesting experiment in which he injected a little muscarin into the jugular vein of a narcotised animal with the effect of at once producing a blanched and anæmic condition of lungs with empty left heart and gorged right ventricle and vena cava. Atropin afterwards injected restored the balance in the circulation. In the case narrated I expect the lungs were during the paroxysm of dyspnœa blanched and anæmic from arterial spasm. Belladonna was not tried, it appears, as a remedy during the time the patient was under my observation as the action of chloral hydrate and subsequently of small doses of Fowler's solution with valerian effected all that was desired.

Welbeck-street, W.

POST-PARTUM HÆMORRHAGE TREATED BY SALINE INJECTION.

BY F. DE JERSEY, M.B., CH.B. GLASG., L.R.C.P. EDIN.,
ASSISTANT MEDICAL OFFICER, WALSINGHAM UNION.

HAVING read the very interesting article on the Injection of Saline Solution in Shock by Mr. Thelwall Thomas in THE LANCET of Nov. 26th I record the following note on a case which came into my hands and which corroborates very markedly what Mr. Thelwall Thomas says—namely, that saline solution acts as a very powerful stimulant to the circulatory system by repleting the circulation and by stimulating the heart.

I was on August 5th, 1898, called to attend a woman, about forty years of age, who was in her thirteenth confinement. On my arrival I found her utterly collapsed, the radial pulse was imperceptible, and she could only be momentarily aroused by shouting at her. She was lying on her back seemingly dead, like a corpse being perfectly blanched, in a mass of liquid and coagulated blood. She must have lost all the blood she possibly could. The child had been born an hour and a half. The delay in my arrival was due to the fact that the patient lived 4 miles away and that the husband had not sent for me soon enough, the child being born shortly after he left home. The after-birth had not come away and seeing the imminent danger that the woman was in and taking into consideration the circumstance that the placenta was not in the vagina and could not be removed by compression of the uterus I concluded that it was adherent, so I at once rapidly prepared some saline solution (1 drachm to the pint of hot water) and injected about 2 pints into the rectum, having previously administered a dose of ergot to arrest further hæmorrhage after the injection. In a very few minutes the radial pulse returned and in about ten minutes the patient opened her eyes and wanted to turn over on her side. Mr. C. E. Gooderson Bateman, the medical officer of the district, being away Dr. Fisher of Fakenham was called in, as I found that the placenta was so adherent that chloroform anæsthesia was necessary whilst its removal was effected. On his speedy arrival chloroform was administered and the after-birth was completely removed. Before leaving the patient the pulse was 125 and very thready. She felt very comfortable and asked for nourishment. In the evening of the same day the pulse was 120 and the temperature was 100·2° F. For a week or more the pulse was rapid and the temperature was about 100°. The woman was a heavy drinker, which was unfavourable to a rapid recovery, but after a somewhat troublesome time she to all appearance completely recovered, leaving the district three months after her confinement.

The hæmorrhage in the above case was undoubtedly due to carelessness. A woman was called in just before the child was born to attend to the patient and in trying to remove the placenta by traction on the cord must have produced a bleeding surface by partially removing it. Seeing that she was doing no good but only producing hæmorrhage she fortunately desisted from making further attempts, but unfortunately lost her head apparently and did not try in any way to stop the bleeding. What could one expect from one of these so-called midwives or women who kindly offer their services on such occasions?

The case is of interest as showing with what great rapidity saline solution acts even if it be injected into the rectum, thence passing up into the bowel by gravitation, where owing to the large absorbing surface the fluid quickly gets into the circulation. It must act like a sponge where a large quantity of blood has been lost.

Walsingham, Norfolk.

PERFORATED GASTRIC ULCER.

BY T. JENNER VERRALL, L.R.C.P. LOND., M.R C.S. ENG.,
SURGEON TO THE SUSSEX COUNTY HOSPITAL.

TWO points of detail in laparotomy for cases of perforated gastric ulcer are worthy, I think, of more stress than is generally laid upon them. Some time ago I lost a patient in whom it was found post mortem that, though the ulcer on the anterior surface of the stomach remained soundly closed as at the operation, another ulcer on the posterior surface exactly opposite the first had given way and hence there had been a fresh outbreak of peritonitis. The interval between the attacks being quite short the ulcer at the back would probably have been discovered if a thorough examination of the stomach had been made at the time of operation. In commenting on this case I suggested that a systematic examination should be made in all cases, approach being

Digitized by Google

obtained through the great omentum. My colleague, Mr. Furner, in a paper on complications arising in this condition, pointed out that subphrenic abscess often followed a focus of infection in the lesser peritoneal cavity. He alluded to my suggestion of opening this cavity as a matter of routine and urged that the liability to subphrenic abscess was an additional argument in favour of adopting this rule. It should be done at the end of the operation, for if flushing has been the mode chosen for cleansing the abdominal cavity portions of septic matter may have been carried through the foramen of Winslow and so have fouled the lesser cavity which was perhaps fairly clean. I hold that flushing with hot saline solution aided by gentle but careful exploration with the fingers of all peritoneal recesses forms the best method of cleansing. Before flushing is begun I insert a glass tube into the pelvis through a separate opening above the pubes. I then cleanse the lower two-thirds of the abdominal cavity and remove portions of food, shreds of lymph, &c., which will have run down largely into the pelvis. After a while the fluid will run out clear as it went in. Turning then to the upper part of the cavity we shall open in succession various recesses with fresh collections, all of which will be swept down and out through the glass tube. By doing this systematically we shall escape much risk of leaving some part uncleansed. When, finally, no fresh clouding of the saline solution is seen we shall know that the peritoneum is clean. I know well that there are cases in which nothing short of sponging will remove adherent lymph, but, as a rule, I believe that the washing and gentle use of soft finger-tips will do as well.

Brighton.

EXFOLIATION OF THE COCHLEA.

BY F. FAULDER WHITE, F.R.C.S. ENG.

HONORARY SURGEON TO THE COVENTRY AND WARWICKSHIRE HOSPITAL.

THE patient was a woman, aged twenty-eight years. She had suffered from a discharge from the right ear from childhood. In September, 1897, she had a severe illness, her account of which is as follows: "It began with severe pain in the ear and right side of the head. I had constant vomiting for twenty-four hours. I became delirious and did not know where I was for several days. The doctors applied ice to the head and poulticed the ear. I was in bed for six weeks." She gradually got better but has been in poor health ever since. The discharge continued to be profuse and was very offensive. She says that her medical attendant told her that it would be very dangerous to check the discharge. She came under my care in October. I found the middle ear full of an offensive discharge and she was quite deaf on the right side. Having admitted her into the hospital I ordered frequent syringing with a hot solution of silico-fluoride. The patient rapidly improved but there were two or three polypi which required removal, and while extracting these my forceps brought away a small piece of bone which was loose in the middle ear. This proved to be the modiolus of the cochlea with part of the osseus spiral lamina. The patient made a rapid and perfect recovery. The ear is now dry and sweet, the inner wall presenting a regular surface, and there is nothing in its appearance to reveal the somewhat unusual deficiency.

Such a case as this shows what nature can sometimes effect without operative interference and every month furnishes me with fresh proof of the reparative powers of the tissues in the middle ear and the adjoining cavities. The vitality of the tissues is lowered by septic organisms, but even after half a lifetime of neglected otorrhœa the middle ear may be restored to health by proper treatment. Yet half the patients who come to me have been under treatment elsewhere without relief or have been professionally advised that it was dangerous to meddle with the ear. Even in works on otology one fails to find any adequate protest against the everyday neglect of this disease. Some aural surgeons, indeed, write as if nothing could be more dangerous, but the hope held out is through operative interference. In uncomplicated cases this is, to say the least, unnecessary.

UNIVERSITY COLLEGE HOSPITAL.

A CASE OF GUMMATOUS ULCERATION OF THE SCALP BECOMING EPITHELIOMATOUS; TREATMENT BY SCRAPING.

(Under the care of Mr. A. E. J. BARKER).

THE chief interest in this case is connected with the occurrence of an epitheliomatous ulcer on the scalp in a patient thirty years of age. The history of the case and the characters of the ulcer when first seen were definitely in favour of a gummatous origin, but the failure of the anti-syphilitic treatment and the histological examination of a portion of the margin of the ulcer proved fairly conclusively that it was epitheliomatous in nature. The phenomenon of a gummatous ulcer developing into a squamous carcinoma is not rarely to be seen in the tongue and occasionally on the lower limbs, but so far as we are aware it has not hitherto been described as occurring on the scalp in a patient of this age.

A woman, aged thirty years, was admitted into University College Hospital on Dec. 2nd, 1896. Four years previously she had had a somewhat prominent pimple on the vertex of her head; this was accidentally pricked with a hat pin and a scab formed; when the scab came off a small ulcer was left. A little later a blind fell on to it and made it bleed. It had been operated on on two occasions at another hospital and she had been treated medicinally, but no real improvement had resulted and the ulcerated area had steadily grown larger. There was nothing in the family history of importance except that an aunt was said to have died from cancer. On admission the patient appeared to be in fairly good health and nothing abnormal was found in any thoracic or abdominal organ. On the vertex of the scalp, rather to the right of the middle line, was a large irregular ulcerated surface measuring about 2 in. in diameter. The margin of the ulcer was crenated and the edge was fairly sharply cut except on the right where it was raised and slightly everted. The depth of the ulcer varied, but towards the right side it was nearly ¾ in. deep. The floor was covered with slough and discharge and at one part there was an evident pulsation. The ulcer was thought to be probably gummatous, though the edge in parts looked epitheliomatous. On admission 5 grains of iodide of potassium were prescribed with tonics and cod-liver oil, and the sore was dressed with sal alembroth gauze. The amount of iodide of potassium was doubled on the 7th and the ulcer was dressed with lotio rubra. The patient was much troubled with constipation which, however, soon yielded to treatment. On the 19th the iodide of potassium was increased to 30 grains three times a day. On Jan. 1st lotio nigra was used to the ulcer, but it appeared to cause a good deal of sloughing, so it was discontinued and lotio rubra was used once more on the 3rd. The ulcer did not make any definite progress, neither did it get any worse. On the 5th the patient complained of severe headache, and caffeine citrate and phenacetin were ordered at night to relieve it. On the 7th the iodide of potassium mixture was ordered to be given in the morning only, and mercurial ointment was ordered to be rubbed into the thighs once a day. The ulcer began to clear up and some of the sloughs separated, and lead lotion was substituted for the lotio rubra, but by Feb. 1st it was evident that very little real improvement had taken place and some fresh small outlying ulcers were noticed. A week later a nitrate of silver lotion (four grains to the ounce) was used. On the 20th, as the ulcer showed no signs of healing, nitrous oxide gas was administered and Mr. Barker removed a small piece of the thickened edge of the ulcer for diagnostic purposes. When this piece was examined microscopically it

Digitized by Google

was found that there were numerous down-growths of the epithelial cells arranged in columns and irregular groups; the cells were squamous in type and a few small cell nests were seen. The anti-syphilitic treatment was persevered in but without any beneficial result and on March 30th, 1897, the patient left the hospital. She was re-admitted on April 20th, 1897, and it was seen that the ulcer had hardly changed in appearance. The surface was covered with pink granulations and at one part there was a small yellowish slough. To the right of the main ulceration there was a small ulcer. Around the larger ulcer the skin was much thickened and the base of the ulcer could not be moved over the bone beneath. At one part the raised margin was nearly a third of an inch above the surrounding scalp. On April 25th, the patient being under ether, the whole mass was thoroughly scraped with a Volkmann's spoon. It was found to be firmly attached to the bone which was in parts eroded and at one spot it was completely perforated, the dura mater being exposed over a space ½ in. in diameter. The skin and tissues around the margin of the ulcer were also removed. The wound was washed with perchloride of mercury lotion, iodoform was dusted over it, and it was dressed with iodoform gauze and wool. Iodide of potassium was given internally at first, on admission 7 grains and later 15 grains three times a day. To this were added 10 grains of iodide of sodium on April 29th. The wound was dressed every other day and healthy granulations soon appeared. On May 7th the wound had diminished in size, was granulating well, and looked healthy, and on the 13th she left the hospital with a small healing ulcer.

ROYAL ALBERT HOSPITAL, DEVONPORT.

A CASE OF DISLOCATION OF THE KNEE.

(Under the care of Mr. F. E. ROW.)

DISLOCATIONS of the knee are by no means frequently seen, for although there is nothing in the shape of the osseous surfaces to keep the bones in apposition the ligaments of the joint are numerous and strong. Of all the traumatic dislocations which may occur at this articulation the lateral is by far the most common. In the case which is recorded below the displacement was partial and it is very rare indeed that complete lateral dislocation is met with and if it does occur the dislocation is almost certain to be compound. The flexion and eversion, which were well seen in this case, are generally present and reduction was effected, as is usual, with great ease, for to permit of displacement both the internal and the external lateral ligaments and the two crucial ligaments must have been torn; there is nothing, therefore, to resist reduction. Persistent weakness of the joint is very liable to occur. For the notes of this case we are indebted to Dr. Daniel Brough, resident medical officer.

The patient, a strong, healthy youth, aged nineteen years, was working a winch at the time of the accident. A heavy weight was being lifted and the rope broke. The handle of the winch flew back and struck him on the outer side of the lower part of the left thigh. On his admission to the Royal Albert Hospital, Devonport, it was at once observed, even before the clothes were removed, that the patient had sustained some unusual form of injury to his knee. On undressing him the following condition of the parts was found. The tibia was displaced outwards and slightly backwards. The external and the greater part of the internal articular surfaces of the head could be defined through the skin. The patella was displaced outwards along with the tibia. The leg lay in a semi-everted position and was slightly flexed and abducted. The lower end of the femur formed a large prominent projection on the inner side of the limb. The internal condylar surface, the intercondyloid notch, and the greater part of the external condylar surface could easily be defined through the skin. The edge of the external condyle rested on the edge of the inner articular surface of the head of the tibia. The skin over the internal condyle of the femur was pale and tightly stretched. A slight abrasion of the skin on the outer side of the thigh marked the spot where the blow had been received. The handle of the winch had evidently struck the femur on the external condyle and driven it inwards. No fracture could be detected and there was no swelling or bruising. The dislocation was reduced under an anæsthetic. The head of the tibia returned to its normal position with a double click, the external condyle of the femur first slipping on to the internal articular surface of the tibia and finally on to the external. The patient has since done well and it is remarkable that very little swelling has ever occurred and no bruising.

Remarks by Dr. BROUGH.—Dislocations of the knee are of comparatively rare occurrence. Great violence is necessary to produce the condition owing to the strength of the joint. The above case is of interest because of the simplicity with which the dislocation was brought about and from the further fact that the bones were separated to a greater degree than is generally the case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Treatment of Separation of the Lower Epiphysis of the Femur.

A MEETING of this society was held on Dec. 13th, Mr. BRYANT, the President, being in the chair.

The PRESIDENT referred to the loss which the society had sustained by the death of Sir William Jenner who was formerly Vice-President and intimated that the council would send a letter of condolence to the members of his family.

Mr. JONATHAN HUTCHINSON, jun., and Mr. H. L. BARNARD communicated a paper on an Improved Method of Treatment of Separation of the Lower Epiphysis of the Femur. They advocated that in all cases of separation of the lower epiphysis of the femur with displacement the treatment with extension of the knee should be given up and they showed by a considerable number of cases with skiagraphic records that it was easy both to obtain reduction and to maintain it by flexing the knee so that the heel touched the buttock. This position was readily tolerated by the patient and after ten days or a fortnight the limb could be put up on a Macintyre splint and subsequently gradually straightened. It was argued that weight extension in the treatment of this injury was quite useless and that the adoption of the full flexion method would not only greatly simplify the treatment, but would lessen the risk of shortening, would secure a better knee-joint, and in some cases might result in saving the limb. Attention was drawn to the disastrous results of compound separation of this epiphysis. Out of 30 collected cases only 6 recovered with a useful limb. The full flexion method was perfectly adapted to compound cases. It was a further development of the plan of treatment on a Macintyre splint flexed to about a right angle and had distinct advantages. It was further maintained that the character of the displacement when the epiphysis was separated was more constant than was generally supposed. The accident occurring when the knee was hyper-extended it was the epiphysis which was nearly always drawn forwards and the diaphysis which projected backwards into the popliteal space. At the same time some rotation or twisting of the leg and corresponding projection of the diaphyseal end was not infrequent. Cases were related in detail illustrating the difficulty of diagnosis and of making certain whether reduction had been properly effected by the old methods and skiagrams were exhibited on the screen proving the persistent tilting forwards of the epiphysis. It was, however, shown that a remarkable moulding and production of new bone occurred in the course of time, so that a much better ultimate result was obtained than might have been expected. Evidence was given that even when some displacement persisted the bone continued to grow in a normal manner. Probably nothing was so likely to damage the epiphyseal disc as prolonged forcible efforts at reduction such as had been recorded in many cases, and Mr. Hutchinson and Mr. Barnard maintained that this risk would be removed by the adoption of the full flexion treatment.

Mr. HUTCHINSON, sen., observed that the paper contained records of a remarkable number of cases of an injury so rare that in twenty-five years' service he himself had never had to treat a single case. The fact that the cases had been drawn from the practice of many surgeons of various hospitals was most gratifying testimony to the harmonious good feeling on such matters which was general at the

Digitized by Google

present day. The method appeared to be one which would facilitate the treatment of a condition which was admitted by all to be a most difficult one to reduce. But he had some misgiving as to whether it would be equally effective in cases where the separation was complete and the ends of the epiphysis and diaphysis were overlapping. When these surfaces were once brought into good position he thought that the straight position would be sufficient to prevent recurrence of the displacement. The method was an application of that used in reduction of vertical displacement of the patella by acute flexion of the limb. He did not think that the displacement of the lower epiphysis of the humerus was altogether similar as the line of bone involved there was narrow, so that to effect reduction was easy but to maintain the bone in place was difficult. He preferred to put such injuries up in a rectangular splint, holding the diaphysis of the humerus back. If the arm were put up in a position of acute flexion the fragment would be likely to be brought too far forward.

The PRESIDENT said that he had seen a few instances of this rare accident, one as far back as his student days, when injuries of the epiphyses were little known. The older writers entirely dwelt on reduction by extension, but extension alone was often less effective for reduction than manipulation, although it maintained the bones in position when once replaced. Reduction by extension would be impossible in some cases probably because the fragment had slipped through a rent in the periosteum. He thought that the suggestion contained in the paper would prove of the greatest value.

Mr. PEARCE GOULD said that the paper showed the value of skiagraphy which enabled Mr. Hutchinson, jun., and Mr. Barnard to give a convincing demonstration of the accuracy of their contentions and therefore left little room for discussion. The merit of the method lay in its making the fragment retrace its steps just as the head of the femur did in the reduction of dislocations of the hip. He agreed with Mr. Hutchinson, sen., that once the reduction was effected there would be little need to maintain the position of acute flexion.

Mr. A. E. BARKER asked if there was any knowledge as to how long the epiphysis took to unite and if any ill effects had resulted from the maintenance of the position of full flexion for long periods.

Mr. BARNARD, in reply, said that in three of the cases separation had been complete, in one the diaphysis being displaced back into the popliteal space and so low as to be on a level with the head of the fibula. As to the necessity of maintaining the flexed position he quoted a case in which relapse of the displacement occurred when the limb was put up on a Liston's splint, and he thought the method of treating it by simply bandaging it in the position of full flexion with a dometto bandage was the simplest, easiest, and most effective. The position caused no discomfort. It should be maintained for a fortnight. Nitrous oxide gas was then administered and the leg was brought down to a right angle and fixed on a Macintyre's splint and extended little by little and finally put up in a plaster case.

MEDICAL SOCIETY OF LONDON.

Transperitoneal Ligature of the Iliac Arteries.

A MEETING of this society was held on Dec. 12th, the President, Mr. EDMUND OWEN, being in the chair.

Mr. BERNARD PITTS read an account of two cases in which he performed Transperitoneal Ligature of the Iliac Arteries. Case 1. Ligature of the Internal Iliac Artery for a Pulsating Sarcoma of the Buttock.—The patient was a man, forty-one years of age, who came under observation in January, 1894, for a pulsating swelling in the right buttock which had first been noticed many months before and had been attributed to a fall. For thirteen months there had been pain down the right leg and latterly numbness as well. When admitted there were signs of pressure on the pelvic nerves, pain along the penis, and incontinence of urine and fæces. The pulsation in the swelling could be diminished by pressure along the iliac crest. The diagnosis lay between pulsating sarcoma and aneurysm and as the signs of pelvic pressure were increasing ligature of the internal iliac artery was decided on. The abdomen was opened in the middle line, the intestine held aside with hot sponges, and an incision made through the peritoneum in the middle line posteriorly. There was some difficulty in reaching the artery as it took an abnormal course. He ligatured it with a gold-beater's skin ligature. There was some diminution in the pulsation of the tumour after ligature which was thought to indicate that it was aneurysmal. On the sixtieth day spontaneous fracture of the right femur occurred and a tumour could be felt in connexion with the liver which left no doubt that it was a sarcoma. Five months after the ligature the right lower limb was amputated and the femur was found to be affected with a small-celled sarcoma invading the medullary cavity. Six months later he was seen very much improved in his general health and able to give some attention to his business. The gluteal tumour and that connected with the liver, however, were larger. A year later he died, the death being attributed to "congestion of the lungs." Mr. Pitts remarked that the ligation of the artery certainly appeared to check the rapidity of the growth. In operating he recommended that the surgeon should first find the common iliac artery and then trace the internal iliac artery. Case 2. Ligature of the Common Iliac Artery for Recurrent Hæmorrhage from a Pelvic Abscess.—The patient was a young man who had had good health till the age of fourteen years when he had a severe boil of the neck, followed by pleurisy and the formation of an abscess (in 1887) in the right lumbar region. He apparently got well and then had an abscess near the insertion of the right deltoid muscle. He remained well for some years except for obstinate constipation. In 1894 he began to complain of pain down the leg and some months later of tenderness in the groin. In July, 1896, the symptoms pointed to trouble round the appendix and there was definite discharge of pus from the rectum which gave great relief for a time, but the symptoms recurred and Mr. Pitts made an incision above the right loin, liberating a small quantity of pus, which was thought to be due to bone trouble. The appendix was found to be healthy. There was a long sinus, but no bone could be felt. In October, 1896, there was swinging pyrexia which disappeared when the sinus was efficiently drained. A short time later there was profuse hæmorrhage from the sinus and as this recurred several times to a dangerous extent Mr. Pitts decided to ligature the internal iliac artery. He operated as in the former case, but the internal iliac artery was surrounded by so much inflammatory matting that he tied the common iliac, using a floss silk ligature. The incision healed well and circulation soon became re-established. The wall of the abscess necrosed and then healed with great rapidity. In December, 1897, an abscess pointed at the lower part of the incision and after a few days the silk ligature was discharged. At the present time the patient was in robust health. Mr. Pitts thought that the original mischief must have been tuberculous disease connected with the lumbar vertebræ. As regards the mode of tying the ligature he believed that the "stay knot" suggested by Mr. Ballance and Mr. Edmunds was the best.

The PRESIDENT congratulated Mr. Pitts both on his paper and on his conduct of the cases. He wondered whether the second case might not have been one of latent septic disease. He asked why gold-beaters' skin had been used in the first case. He himself did not see that it had any advantage over silk which could always be obtained. He asked whether the medullary growth in the femur was supposed to be secondary to the pelvic growth. The case would encourage the surgeon not to wait unduly till the diagnosis between sarcoma and aneurysm was made with certainty as the sarcoma seemed to have been checked by the ligation of the artery.

Mr. HARRISON CRIPPS remarked that a transverse incision of the abdominal wall should be avoided wherever possible as it was almost impossible to avoid the occurrence of a hernia when it was adopted. As to the kind of ligature he preferred to use a smaller size than Mr. Pitts had employed, such as a No. 2 silk ligature. In ligaturing the stump of an ovarian tumour he used fine silk. He did not think that if the tumour were known to be a sarcoma it would be prudent to ligature the large arteries. In operating in one case, that of a stout man, sixty years of age, for the relief of an aneurysm of the size of a cocoanut in the groin he opened the abdomen along the left border of the left rectus muscle. He attempted to reach the artery through an incision on the inner side of the descending colon. Owing to the amount of fat on the abdominal wall he was not able to reach it, but did so with ease by making his incision through the peritoneum on the outer side of the gut.

Mr. MARMADUKE SHEILD thought that the second case

Digitized by Google

was most likely one of chronic pyæmia such as had been described by Sir James Paget. If it had been tuberculous he thought it unlikely that his general condition would have improved so much after the operation. Possibly the infection was from the boil in the neck. He mentioned the case of a man who had antral disease supposed to be due to influenza in whom a year later there was suppuration in the glands and other structures in the neck. No tubercle bacilli could be found, but there was abundant growth of staphylococcus aureus. The latency of organisms in the tissue was remarkable and was often well seen in the case of deep-seated mammary abscess. He had long ago advocated reaching the iliac vessels in the way successfully carried out by Mr. Pitts. As regards the material of the ligature he preferred a soft ligature and thought that silk was more satisfactory than catgut or kangaroo tendon.

Mr. BALLANCE observed that in 1890 he and Mr. Edmunds had fully described this mode of operating. He asked why Mr. Pitts incised the peritoneum in the middle line behind instead of along the line of the artery. He thought that on the whole soft silk was the best material for ligature, which should not be too fine or it cut through the coats. He found gold-beaters' skin which was prepared from the peritoneum of the ox another excellent material for ligatures. It could be obtained from Messrs. Macfarlane made up as ligatures in a round and supple form. A ligature of the same size as No. 4 silk would last 150 days in the body. In the Museum of St. Thomas's Hospital there were two specimens of ovarian pedicles. In the first, eighteen months after operation, all the ligature except the knot had been absorbed, and in one three years after the whole ligature had disappeared.

Dr. JOHN BRUNTON observed that silk ligatures were often adulterated with jute which could be distinguished by its woody odour when burned and by its microscopical appearances.

Dr. LYNDON said that the second patient had been under his care for the last eighteen months. He thought that the case was one of tuberculosis, although when there was discharge of pus at the time of the extrusion of the ligature he failed to discover tubercle bacilli.

Mr. PITTS, in reply, said that he was strongly in favour of the view that the case was tuberculous. He did not know of cases where septic material remained dormant for so many years with only short periods of activity. He thought that the patient's present robust condition was quite compatible with his having recovered from a tuberculous affection. He did not find any objection to the use of silk ligatures and preferred not to have them too fine in order to avoid injuring the coats of the artery. He still thought that a median incision was best for reaching the vessels if they were in their normal position. He had no doubt that the tumour in the femur was a secondary deposit.

CLINICAL SOCIETY OF LONDON.

Chancre.—Pancreatic Calculi.—Acute Hæmorrhagic Pancreatitis.

A MEETING of this society was held on Dec. 9th, Mr. LANGTON, President, being in the chair.

Mr. CAMPBELL WILLIAMS read a paper on a case of Lingual Chancre from Indirect Contagion which tended to show that the virus of syphilis could remain active in the dried state for over two months. The vehicle for the dried virus was the mouthpiece of a set of bagpipes which had been played upon by a syphilitic subject and then put away for two months, when the owner used them and developed a hard sore of the tongue and the usual secondary syphilitic sequelæ, the chancre appearing either twenty or thirty days after the presumptive infection. The only other solution of more recent exposure to some other source of infection was strenuously denied. The history of the case was in favour of the patient's statements and condition.—Mr. CLEMENT LUCAS said that the details appeared to be too exact to allow of doubt as to the correctness of the explanation. There was no more improbability in the preservation of dried syphilitic virus than of dry vaccine virus on the old ivory points. He mentioned the case of a man, nearly sixty years of age, in whom a chancre occurred on an abrasion of the tongue caused by a dental plate and in which he believed the infection to have been accidental through a tumbler or pipe contaminated by some syphilitic person.—Mr. CAMPBELL WILLIAMS, in reply, mentioned another case in which a patient had a chancre on a pimple over the trochanter almost certainly caused by infection from the seat of a closet.

Mr. A. PEARCE GOULD read a paper on a case of Pancreatic Calculi one of which obstructed the bile-duct. The patient was a man, forty-six years of age, whose only previous illness was influenza four years before. In September, 1895, he noticed some failure in health and in November he suffered for a few days from severe pain referred to the umbilicus, chiefly felt on walking up hill. He became jaundiced and this persisted until February, 1896, when he came under observation. The liver was then enlarged nearly down to the umbilicus and the gall-bladder could be felt distended as a cylindrical swelling in the right lumbar region. There was no ascites. The motions were of a clay colour. On Feb. 14th Mr. Gould explored the abdomen through a vertical incision to the right of the rectus muscle. Half a pint of fluid was drawn off from the gall-bladder by aspiration. A lump was felt at the back of the small omentum which proved to be a coral-like stone in the dilated duct of Wirsung and other smaller calculi were found and removed. The operation did not relieve the obstruction to the flow of bile and on March 3rd the patient had an attack of agonising pain in the right hypochondrium. Mr. Gould re-opened the abdomen and with some difficulty was able to feel a stone in the head of the pancreas close to the duodenum which he removed by incising the pancreas from the front, and he was then able to pass a probe through the duct into the duodenum. Soon after the operation the patient vomited bile, the stools became coloured, and bile ceased to flow from the incision in the gall-bladder. Notwithstanding vomiting persisted and he died from exhaustion the twelfth day after the second operation. Post mortem a little pus was found underneath the gall-bladder and also behind the ascending colon. The pancreatic duct was found to be dilated and ulcerated. There was a hydatid cyst at the back of the liver. The calculus was composed of phosphate and carbonate of lime.—Mr. T. H. KELLOCK mentioned a case which was under the care of Dr. Ord at St. Thomas's Hospital some years ago. A man, aged fifty-six years, was seized with acute abdominal pain followed at once by jaundice. Two weeks later there was a second attack. When admitted he was extremely jaundiced and the liver reached from the third rib to below the costal margin. On the tenth day he had a rigor followed by severe pain in the right hypochondrium and three days later he passed a small concretion. The jaundice became less marked after the passage of the calculus but he became exhausted and gradually sank. Post mortem the liver was found to be enlarged and the gall-bladder was dilated. Embedded in the head of the pancreas in a dilated portion of the duct was another calculus of the size of a cherry-stone.—The PRESIDENT remarked that jaundice was one of the most patent features in Mr. Gould's case and asked how close the calculus was to the opening of the duct.—Mr. GOULD, in reply, said the stone lay in a cavity half an inch before the union of the ducts and would press on both. That it caused the jaundice was shown by the passage of bile at once after its removal and the disappearance of the jaundice.

Mr. A. D. FRIPP and Dr. J. H. BRYANT related a case of Acute Hæmorrhagic Pancreatitis. The patient was a man, aged forty-two years, admitted to Guy's Hospital on Sept. 18th, 1898. He was seized with pain two days before and was admitted in a state of collapse. The pain was chiefly above the umbilicus. An exploratory laparotomy was performed at once. No obstruction was found. There was a good deal of blood-stained peritoneal fluid; the omentum had a shotty feel, but no necrotic nodules were found. There was extreme contraction of the small intestine in places. The abdomen was closed and the patient died forty-eight hours later. The necropsy was performed eleven and a half hours after death. The abdominal wall was very thick owing to the great increase of subperitoneal and subcutaneous fat. The omentum was large and thick. Extensive fat necrosis was found in the omentum, mesocolon, fat around the pancreas, and the subperitoneal fat both visceral and parietal. There was extensive hæmorrhage into the fatty tissue around the pancreas in the gastro-splenic omentum. The pancreas was of about twice its normal size; it was of a dull, dark, purplish colour, and on section appeared to be infiltrated with blood. Patches of fat necrosis were also visible in the interlobular tissue of this organ. The stomach, duodenum, and the rest of the intestine presented a normal appearance except for a little ecchymosis around the cardiac orifice of the stomach. The heart weighed 13 oz.; the valves and

Digitized by Google

blood-vessels were normal in appearance. On microscopic examination the most striking changes noticed in all the sections was the enormous amount of blood present, which could be seen in large quantity beneath the capsule of the pancreas, in the interstitial tissue between the lobules, between the acini themselves around the ducts, and in the fat cells and intercellular spaces of the peri-glandular connective tissues. A good many patches of fat necrosis were seen in the interlobular and peri-glandular tissues. The glandular acini immediately adjacent to these areas were in various stages of necrosis and beyond these again the cells of the acini showed cloudy swelling and their nuclei were faintly stained and indistinct. Apart from these areas there was very little evidence of any parenchymatous inflammation, the nuclei and protoplasm of the cells staining well with the various reagents. The pancreatic ducts were not obstructed; the cells presented a normal appearance. In the fibrous tissue of, and around the, ducts a good deal of blood was seen. The fat necrosis presented the usual features characteristic of that condition. Sections stained with methylene blue showed a few rod-shaped bacilli in the blood throughout the organ. There were no bacilli in the pancreatic ducts. Sections of the nerves and ganglia from the pancreatic duodenal plexus were examined, but nothing abnormal was found. Cultivations were taken from the centre of the body of the pancreas with strict precautions to prevent the possibility of any accidental contamination and a pure culture of the bacillus coli communis resulted. The pathological process in this case appeared to be a primary acute interstitial inflammation associated with the presence of the bacillus coli communis and characterised by extensive hæmorrhage as stated above and by secondary necrosis and inflammation of the parenchyma in the immediate vicinity of areas of fat necrosis. The distribution of the bacilli suggested the blood-vessels as the probable channel of infection. Two other cases were mentioned in which bacteriological examinations were made by Mr. Pakes, demonstrator of bacteriology at Guy's Hospital, the bacillus coli communis being obtained in pure culture from the pancreas in both instances. A similar fully reported case by Dr. Moore[1] was referred to in which a pure culture of the bacillus coli communis was also obtained and in which the channel of infection was thought to be the lymphatic spaces. (Microscopical specimens were shown demonstrating the above-mentioned observations.)

Dr. NEWTON PITT and Mr. JACOBSON communicated a paper on Five Cases of Acute Pancreatitis. Case 1. Acute Hæmorrhagic Pancreatitis.—A man, aged forty-two years, temperate, had three attacks of severe abdominal pain with vomiting, each lasting about an hour, in August and September, 1898. On Nov. 12th he had another attack of intense pain with vomiting and constipation. The pulse was 120 and the abdomen was rigid. On the 14th he had severe diarrhœa, his temperature was 100° F., and there was a swelling in the upper part of the abdomen. He was seen by Dr. John Young of Stamford Hill who took him to Guy's Hospital. The man was extremely ill and difficult to examine. A retro-peritoneal tumour with impaired resonance was found above the umbilicus, the motions were normal in colour, but the man was so ill that it was thought better to defer any operative interference. On examination the urine was found to contain albumose; there was marked leucocytosis (22,500 per cubic mm.), and the tumour lay behind the stomach pushing forward the duodenum and greatly distending the former. The evidence pointed to a pancreatic cyst or an abscess in connexion with either pancreas, gall-bladder, or gastric ulcer, or a rapidly growing sarcoma. As the tumour was increasing in size Mr. Jacobson decided to open the abdomen and found extensive fat necrosis and a tumour with the lesser omentum, intestines, and stomach matted to it. The oozing from every part when disturbed was excessive and the firm feel of the mass prevented any radical treatment. The abdomen was closed and the patient died next day. Post mortem there was found an abscess cavity some 4 in. across, in front of which was the stomach and lesser omentum and behind lay the sloughy pancreas. Case 2. A Retro-gastric Pancreatic Abscess.—A middle-aged woman was seen by Dr. Pitt some years ago for intense abdominal pain and vomiting. She was found to have a large abscess behind the peritoneum pointing in the right loin where it was opened. Most of the pancreas had disappeared; the abscess occupied its site. It was now clear this was a case of acute pancreatitis. Case 3. Acute Hæmorrhagic Pancreatitis.—A woman, aged seventy years, was seen by Mr. Fuller of Streatham on Oct. 16th, 1898, for intense epigastric pain with sickness and collapse occurring after an unusually good breakfast. The pain was not relieved by the vomiting. There was a constant desire to defecate, which was not relieved by an enema which brought away a constipated motion containing particles of fat. There was slight tympanites which steadily increased until death, forty-eight hours later. The patient was said to have had a similar attack eighteen months previously. At the necropsy acute hæmorrhagic pancreatitis was found, with fat necrosis of the omentum. Case 4. Acute Suppurative Pancreatitis.—The patient was a man, aged fifty-three years. He was an alcoholic. On Nov. 12th, 1863, at 2 A.M. he took a draught of cold water; at 3 A.M. he was seized with intense epigastric pain with vomiting. The symptoms subsided on the 17th. On the 24th a pulsating tumour imperfectly resonant on percussion was noticed above the umbilicus; this became less distinct in the knee-elbow position and the pain ceased. The vomiting returned at the end of January and he died on February 8th from exhaustion. At the necropsy it was found that the omentum formed a black puckered mass; the stomach was greatly distended; the lesser sac of the omentum contained a well-defined abscess above and behind the stomach. The greater part of the pancreas was healthy, but some distended ducts communicated with the abscess. Case 5. Acute Necrotic Pancreatitis.—A man, aged sixty years, had had severe abdominal pain and vomiting for three months, the attacks recurring every three or four days. For four years he had had attacks of gastric pain from time to time. On admission under the care of Dr. Habershon there was a tender pulsating tumour in the upper part of the abdomen. The patient vomited frequently and died from exhaustion. At the necropsy some early peritonitis was found; a minute opening was also found in the meso-colon leading to an abscess cavity behind the stomach and filled with a brown fluid. At the posterior part of the abscess 2½ in. of necrotic pancreas was found. There were numerous nodules of yellow concrete matter in the wall of the cyst (probably fat necrosis).—The PRESIDENT related a case in which the symptoms might have been due to a milder form of the same disease. A man, fifty years of age, was seized with umbilical pain and afterwards a tumour formed extending from the ensiform cartilage to the umbilicus. Vomiting and diarrhœa were present and the patient wasted rapidly. Ascites was present but after the fluid was removed by aspiration it did not return. The tumour could be felt much more distinctly after aspiration and three weeks later the abdomen was explored. A cystic tumour was found behind the stomach which Mr. Langton aspirated and five pints of blood-stained fluid were drawn off. The cyst evidently involved the pancreas. The patient made a fair recovery but died suddenly from intestinal hæmorrhage two years later. Post mortem the pancreas was found to be nearly entirely destroyed and then it was also found that the cicatrix of the contracted cyst had involved the portal vein, thus accounting for the hæmorrhage.—Mr. BOWLBY said that several causes of this condition were recognised—injury, infective inflammation, and he thought probably embolism. The sudden onset and the necrotic state of the pancreas would be explained by such a causation. He asked if the condition of the pancreatic artery in this case had been investigated. He mentioned a case in which a woman, aged forty-one years, was suddenly seized with symptoms pointing to intestinal obstruction. He opened the abdomen 48 hours later but found no obstruction. The omentum, however, was dotted over with areas of fat necrosis. The pain was relieved by laparotomy but on the third day she suddenly became delirious and died comatose. Although there was no necropsy he had little doubt that she suffered from acute pancreatitis.

OBSTETRICAL SOCIETY OF LONDON.

The Development of the Graafian Follicle.—Uterine Fibroids.—Congenital Tumour at the Internal Os causing Hydrometra.—Incarcerated Ovarian Dermoid Tumours during Pregnancy,—Placenta Prævia and Fibroids.—The Actions and Use of Forceps.

A MEETING of this society was held on Dec. 7th, Dr. C. J. CULLINGWORTH, President, being in the chair.

Digitized by Google

Dr. HUNTER gave a demonstration of specimens illustrating the Development of the Graafian Follicle and exhibited a series of ovaries preserved in formalin in which the colours were well maintained.

Dr. LEWERS showed (1) a large Solitary Subperitoneal Fibroid Tumour of the Uterus (9½ lb.) successfully removed by laparotomy with intra-peritoneal treatment of the stump; (2) a Uterus with Multiple Fibroids (8 lb.) successfully removed by supravaginal hysterectomy with intraperitoneal treatment of the stump. He said that as regards the history, symptoms, and signs cases of large solitary subperitoneal fibroids differed remarkably from the common cases where the uterus was the seat of multiple fibroids. In the first case the patient, married ten years, had had five children and two miscarriages, the last ten months prior to operation. Menstruation had never lasted more than two days and for ten months prior to operation there had been complete amenorrhœa. The uterus was in no way deformed except at the place where the tumour was attached and the cavity was of normal length. In the second case the patient, married five years, had not been pregnant. Menstruation was profuse and there had been constant metrorrhagia for three months before operation. The uterus was deformed and the sound passed 7 in. or 8 in.

Dr. HERBERT SPENCER read a short communication on three cases of Congenital Tumour at the Internal Os Uteri causing Hydrometra in Newly-born Children. Two of the specimens had been briefly described in the catalogue of the gynæcological specimens in University College Museum published in 1891 and were, as far as he was aware, the first recorded instances of the occurrence of this tumour. The tumour was a small sessile, pea-like body situated at the summit of the anterior median column of the cervical arbor vitæ and gave rise to dilatation of the cavity of the body by obstructing the outflow of mucus. Dr. Spencer thought the tumour might later in life produce pain at menstrual or at other times and might perhaps explain the occurrence of certain polypi at the internal os uteri which were furnished with glands lined with several layers of epithelium—a condition which he had met with in this situation in newly-born children. He directed attention to a recent publication by Dr. Friedländer[1] on a similar condition in young girls.

Dr. HERBERT SPENCER showed a small Multilocular Dermoid Tumour of the Right Ovary which being incarcerated in the pelvis he had removed by laparotomy at the fourth month of pregnancy. Pain which had been present before the operation at once ceased on removal of the tumour and the patient had five months later been successfully delivered of a living child at full term.

Dr. HERBERT SPENCER also showed for another practitioner a small Ovarian Dermoid Tumour which had been incarcerated in the pelvis at the time of labour. Forceps and afterwards version had been employed with the result that the tumour was ruptured and the patient died from septic peritonitis three days after delivery.—Dr. JOHN PHILLIPS said that he had met with a case in which the cyst had obstructed labour and necessitated its incision and suturing to the vaginal walls before delivery could be effected. A year later the patient was seized with a rigor and abdominal pain and at the operation a large suppurating dermoid cyst was found with a coil of hair adherent to the old scar in the vagina. The patient made a good recovery. Dr. Phillips had recently had an impacted dermoid complicating early pregnancy which had been successfully removed.—Dr. GILES mentioned a case of an ovarian dermoid removed during pregnancy. He first saw the patient when she was three months pregnant and decided to wait and see whether with the progress of pregnancy the cyst would rise out of the pelvis; as this did not happen the cyst was removed by abdominal section and the patient was expecting her confinement shortly.

Dr. BOXALL showed a Uterus with Interstitial Fibroids from a case of placenta prævia centralis. The patient died forty minutes after delivery from acute and post-partum hæmorrhage. In her previous confinement three years ago a large fibroid was noticed in the lower pole of the uterus on the left side and an abscess formed and burst into the vagina, the sinus in which still remained. The fibroid had shrunk considerably since the previous labour.

A paper by Dr. PONDER on the Actions and Use of Forceps gave rise to some discussion.

OPHTHALMOLOGICAL SOCIETY.

Renal Retinitis.—Sympathetic Ophthalmia beginning fourteen days after Excision of the Injured Eye.—An Unusual Form of Marginal Keratitis.—Pulsating Exophthalmos with Visible Tumour.—Symmetrical Choroiditis in the Early Stage.—Atrophy of the Choroid with Sclerosis of the Choroidal Vessels.—Myxo-sarcoma of the Orbit.—Congenital Absence of the Choroid.—Tumour of the Iris.—Injury to the Cornea.

A CLINICAL meeting of this society was held on Dec. 8th, Mr. H. R. SWANZY being in the chair.

Mr. NETTLESHIP showed a microscopical drawing of Renal Retinitis. Pigmentation of the retina was known to occur in cases of renal retinitis where the disease was either severe or of long standing; it was generally seen near the periphery, but if the case lasted long enough it was also found near the disc. The case from which the drawing was taken had been observed during life and the pigmentation had been noted. After death the eyes had been examined. A number of oval or round cells, with amorphous débris the remains of an inflammatory exudation, were found in the retina between the bacillary layer and the hexagonal pigment layer in different places; these foci contained pigmented cells derived from the pigment epithelium, probably by proliferation.

Mr. HOLMES SPICER showed a case of Sympathetic Ophthalmia beginning Fourteen Days after Excision of the Injured Eye in a boy, aged ten years, who was struck in the left eye on July 4th by a piece of sardine tin; there was a jagged wound of the cornea not involving the ciliary region; the anterior chamber was filled with blood and the deeper parts could not be seen. A week later, July 12th, a piece of entangled iris was removed from the wound by iridectomy; the lens was found to be wounded. The eye remained painful and much congested and iritis set in and it was excised on July 25th, three weeks after the injury. The patient remained in hospital till August 6th. Two days later there was slight ciliary injection of the right eye. Fourteen days after excision he was taken into hospital again. Tension was − 2, and the vision equalled $\frac{6}{36}$; the pupil was well dilated; there was no deposit on the back of the cornea; there was much floating matter in the anterior part of the vitreous; there was no optic neuritis. He was treated with atropine and mercurial inunction. The tension had now become normal and the vision was $\frac{6}{9}$.

Mr. JOHN GRIFFITH and Dr. C. S. BLAIR showed a case exhibiting an Unusual Form of Marginal Keratitis. The condition had existed for several years and was associated with eczema of the face; the keratitis was symmetrical, attacking the inner and outer margins of each cornea close to the limbus. The lesions were slightly raised, vascular, and in three out of four limited by a curved line of opacity. It bore some resemblance to phlyctenular keratitis, but its persistence, absence of ulceration, and want of symptoms excluded this disease. It resembled spring catarrh, but the palpebral conjunctivæ were quite healthy.

Mr. W. J. CANT showed a man, aged thirty-six years, having Pulsating Exophthalmos with Visible Tumour who was kicked on the outer part of the left eyebrow eight years ago. Eighteen months ago he had pain over the right eyebrow with vomiting; the sight became dim and he had diplopia. Gradually a swelling appeared at the upper inner angle of the right orbit and he was conscious of a loud whistling sound in the head; as the swelling increased the sight returned and the diplopia ceased. The vision of the right eye equalled $\frac{6}{9}$ and Jaeger 1, and there was proptosis to the extent of 8 mm. There were large tortuous veins on the ocular conjunctiva and a pulsating moveable tumour diminished by pressure on the carotid; a loud bruit could be heard over the region of the tumour. There was no diplopia; the pupil acted normally; the retinal veins were enlarged, tortuous, and pulsating. He had been treated with rest, low diet, iodide of potassium, and digital compression with considerable benefit.

Mr. HARTRIDGE showed a man, aged twenty-three years, with Symmetrical Choroiditis in the Early Stage who first had dimness of sight five months ago; the sight had been progressively failing since. The family history and the personal health were good and there was no history of syphilis. The vision of the right eye equalled $\frac{6}{9}$ and of the left $\frac{6}{12}$. Both optic discs were swollen and blurred; there was a large choroidal hæmorrhage on the outer side of each

Digitized by Google

disc and œdema of the retina over the whole central region, with a number of small circular exudations in the superficial layers of the choroid; the urine was normal.

Mr. ERNEST CLARKE showed a man, aged fifty-three years, exhibiting Atrophy of the Choroid with Sclerosis of the Choroidal Vessels who first attended the Central London Ophthalmic Hospital four years ago with the history that his sight had been gradually failing for a year. He had been a heavy drinker and had had syphilis. He had well-marked optic neuritis in both eyes and vision was reduced to perception of fingers at a metre in both eyes; there was no history of night blindness. The following changes had been gradually coming on since then and the present condition of the eyes was as follows: atrophy of the optic nerve and retina, atrophy of the epithelial pigment and of the chorio-capillaris, which allowed the vessels in the tunica vasculosa to be well seen; sclerosis of many of the choroidal vessels, especially on the temporal side of the posterior pole of each eye. The periphery of the retina showed pigmentation like that of retinitis pigmentosa. There were large flocculent vitreous opacities. Vision was reduced to perception of light.

Mr. JULER showed a case of Myxo-sarcoma of the Left Orbit in a woman, aged twenty years, with microscopic sections and photograph. The patient had always been healthy till May, 1897, when diplopia set in. In February, 1898, the left upper lid began to droop and the eyeball seemed to be turned downwards and pushed forwards. Since then the globe had been gradually displaced downwards, forwards, and outwards. At the time of admission to the hospital (June 15th, 1898) there were marked ptosis and proptosis, the globe protruding about 2 cm. forwards and 3 cm. downwards and slightly outwards. The movements of the globe were greatly limited. The tumour caused bulging of the upper lid; it was softish and semi-fluctuant; about the centre could be felt a rather hard nodule and another towards the inner portion. The cornea was hazy, but the fundus appeared to be normal. The conjunctiva was congested. Vision was reduced to perception of fingers. The skin of the face was sprinkled with brown and blue pigmented spots. These the patient asserted had always existed. The tumour was removed on June 25th with the whole contents of the orbit. Before removal a trocar and cannula were inserted into the depths of the tumour and gave exit to several drachms of clear, gelatinous-looking fluid. Incision into the tumour discovered a cyst in its midst. After removal of the orbital contents the bone at its roof was found to be corroded and an aperture extended to the dura mater. Hæmorrhage was stopped by thermo-cautery and plugging with antiseptic gauze. The patient made a good recovery without constitutional disturbance and was discharged on July 29th. She progressed favourably and without pain until November when she noticed a slight swelling beneath the upper lid. This increased in size and she came back on Dec. 8th presenting a hard, nodular, thickened growth beneath the upper lid which was evidently fixed to the roof of the orbit and blocking up the whole orbital cavity. The tumour had been examined microscopically by Mr. John Griffith and Mr. Juler who considered that it presented the characteristics of a benign myxoma, being composed of stellate cells branching and anastomosing in all directions, round cells, and blood-vessels. Within the stroma mucin was held as water within a sponge. The lacrymal gland was enlarged and infiltrated in places with round cells, either inflammatory or sarcomatous. The muscular fibres were swollen and split transversely, as in Zenker's degeneration. A piece of skin containing one of the blue spots showed only collections of pigmented cells clustered around the hair follicles in the true skin. The microscopic examination of the tumour alone would have led to the hope of perfect recovery after its complete removal. The fact, however, of the frontal bone being corroded and even perforated prevented more active operative interference and rendered recurrence more than probable. With regard to the future treatment of the recurrent growth Mr. Juler could not speak favourably as the frontal bone was certainly infiltrated and the sarcoma had probably already invaded the dura mater and frontal lobe of the brain.

Dr. TATHAM THOMPSON showed a man, aged eighteen years, exhibiting Congenital Absence of the Choroid. The vision equalled $\frac{20}{200}$. Examination by the ophthalmoscope showed a dazzling white sclera all over the fundus except at the macula; there were a few isolated choroidal vessels only.

Mr. A. H. THOMPSON showed a small Tumour, probably a Sarcoma, projecting from the anterior surface of the iris.

Mr. W. H. JESSOP showed a case of Injury to the Cornea. A large flap turned back from the upper margin of the cornea had become re-applied and united.

BRITISH GYNÆCOLOGICAL SOCIETY.

Pelvic Surgery.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 8th, Dr. H. MACNAUGHTON-JONES, President, being in the chair.

Mr. E. STANMORE BISHOP (Manchester) read a paper on the Combined Abdominal and Vaginal Section in certain cases of Pelvic Surgery. The first case was that of a woman, aged twenty-eight years. With her second child she had a premature labour due to fright followed by severe hæmorrhage. She had a miscarriage two years ago, followed by persistent bleeding. Two months ago she had smart bleeding with excessive pain on the left side which was becoming more acute. There was a small firm mass in the ovarian region which was very tender. It was removed by combined operation, it being too firmly fixed to be brought down per vaginam. It adhered by omentum to the pelvic brim. The patient recovered. The second case was that of a woman, aged forty-six years. Her second child was born twenty-two years ago. Menstruation since then had been irregular and profuse, the quantity increasing. Sacral and hypogastric pain was also increasing. She had been bedridden for fourteen months. There was double pyosalpinx. It was removed by combined operation because even after complete division of the uterus per vaginam the parts were too rigid to allow of their being drawn down. On abdominal section two large pus sacs were found with adherent intestine. The patient recovered. The third case was that of a woman, aged twenty-nine years. She had had no pregnancies. There was a history of scarlet fever. She caught a chill during menstruation. She had had no period for fifteen months, had had loss of flesh for twelve months, had been bedridden for ten months, and had had night sweats for nine months. Her left leg was fixed in flexion. It was œdematous. There was double pyosalpinx. It was removed by combined operation because the parts were too fixed, even after total section of the uterus, to allow of their being drawn downwards. On abdominal section the small intestine was found to be adherent to the tube, bladder, and iliac fossa. The right ovary was found —a thick-walled abscess—separate from the rest and embedded in adhesions in the right iliac fossa. The patient died. The fourth case was that of a woman, aged thirty-nine years. She had had several miscarriages and no full-time pregnancies. She had increasing menorrhagia and metrorrhagia. There was much pain. The uterus was enlarged to the size of six months pregnancy; it was partly soft and partly intensely hard. The uterine canal was elongated and a fibroid tumour was found. It was removed by combined operation because the patient being very anæmic it seemed advisable to render the operation as bloodless as possible by tying the uterine arteries at the earliest possible moment and by doing most of the work from below to shorten the time during which the peritoneum should be open. When this was done abdominal section was performed so as to shorten as much as possible the entire duration of the operation. These cases were selected because each illustrated some points in the question under discussion. Thus the first case showed the difficulty which sometimes arose in the removal of even a small tumour through the vagina when it was adherent above and there was no justification for removal of the uterus. The second case showed that even when the uterus could be removed with the tubes there might still be great risk in doing this through the vagina alone when intestinal adhesions were present. The third case showed the impossibility in some cases of removing all foci of suppuration without the double attack, whilst the fourth case illustrated the advantage gained in an operation intended to be finished by abdominal cœliotomy by performing the earlier steps per vaginam—advantages in time and in minimisation of shock. Mr. Stanmore Bishop proceeded to review the advantages of abdominal and vaginal cœliotomy and their several disadvantages. He pointed out that many of the disadvantages originally present in the abdominal operation had now been eliminated by improvements in position, technique, &c., whilst the vaginal

Digitized by Google

operation, which at first appeared to avoid all these, was unsuitable in certain cases and had certain dangers of its own. He emphasised, however, certain marked advantages which it undoubtedly possessed. He advocated the combination of both methods in some cases in which it was impossible or inadvisable to finish the operation from below and deprecated the "morcellation" recommended by Landau. This manœuvre, he suggested, should not bear the same name as that of the older operation, devised by Péan and designed for the removal of single fibroids per vaginam, through the dilated os, which left the uterus intact and useful. He advised it also in cases which must be finished through the abdomen in order to diminish the amount of shock. He invited the society to define the limit beyond which the vaginal attack should not be carried.

Dr. HERBERT SNOW observed that in only one of Mr. Bishop's cases was the combined method deliberately adopted; in the other 3 it was done as a matter of necessity and he thought most of the Fellows would feel that in these 3 cases it would have been better to begin by the abdomen. He did not agree with Mr. Bishop that mere laparotomy meant much shock; most of the cases originally described as shock were really cases either of concealed hæmorrhage or of septic peritonitis. He doubted if any advantage of the combined method would compensate for the drawback of proceeding to laparotomy after the hands had become soiled with pus and mucus in the vagina.

Mr. MAYO ROBSON (Leeds) thought it was best to make up one's mind beforehand which route to adopt; at the same time every operator ought to be prepared to follow up one route by the other. His experience was that it was only rarely necessary to complete by the abdomen an operation begun by the vagina. As a rule, in a case of hysterectomy if he found that he could not bring the uterus down he would prefer not to operate at all, for in such cases life was probably not prolonged. For most cases he preferred the abdominal route.

Mr. BOWREMAN JESSETT agreed with the previous speakers that it was better to determine beforehand which route to adopt, but this was not always possible except under anæsthesia. If such an examination showed that there was much fixation, he thought it better to proceed at once to laparotomy.

Mr. J. W. TAYLOR (Birmingham) pointed out that there were two distinct questions in the paper: (1) the combined method in the treatment of myoma; and (2) the same in the treatment of inflammatory conditions. For myomata the operation was a valuable one because it was often safer to secure the uterine arteries through the vagina as the first step, and also the duration of the operation was thereby shortened. In inflammatory conditions they did not yet know how much could be done by the vagina but were still learners.

Mr. J. FURNEAUX JORDAN (Birmingham) approved of the combined method for hysterectomy for the reasons given by Mr. Taylor and also because the work done by the vagina was extra-peritoneal. Most other cases could be dealt with by one or the other route and he agreed that in such cases it was better to decide beforehand which to adopt. He had done about 10 vaginal cœliotomies; in 1 he had to open the abdomen after all, but in most cases a careful diagnosis beforehand would obviate this necessity. For inflammatory conditions the abdominal route was usually the best, but pyosalpinx operated on by laparotomy had such a high mortality that some palliative vaginal procedure was often better.

Dr. MACPHERSON LAWRIE (Weymouth) thought the cases requiring the combined method must be few and far between.

Dr. HEYWOOD SMITH questioned whether Mr. Bishop's contention that the combined method was quicker would be found generally true.

Dr. PURCELL stated that the double method originated with Martin who was, however, so unfortunate in his early cases that he gave it up.

Dr. ARTHUR GILES remarked that the *raison d'être* of the vaginal operations was to obviate the necessity of opening the abdomen. There was nothing which was done by the combined method that could not be done by the abdominal alone.

The PRESIDENT said that Mr. Bishop was forced to the consideration of the combined method by cases in which operation had been too long delayed. He should have felt inclined to operate through the abdomen in the first instance in these cases. The society was much indebted to Mr. Bishop for his paper which dealt with some of the most recent work in gynæcology.

Mr. STANMORE BISHOP briefly replied.

The following specimens were shown:—

Mr. CHARLES RYALL: (1) Myoma Uteri complicated with distended tube and broad ligament cyst; and (2) a Large Fallopian Tube.

Dr. MACPHERSON LAWRIE (Weymouth): (1) Fibroid Uterus removed by Subperitoneal Hysterectomy; and (2) Fibroid Uterus undergoing malignant degeneration.

Mr. J. W. TAYLOR (Birmingham): (1) Small Myoma removed from the fundus after anterior colpotomy and division of the uterus; (2) two small Ovarian Cysts, each removed by posterior colpotomy; and (3) Tubal Mole with right Fallopian Tube removed by posterior colpotomy.

Dr. F. A. PURCELL: Uterine Carcinoma removed by Vaginal Hysterectomy.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Treatment of Shock.—Paralysis of Laryngeal Abductors.—Abdominal Section.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Dec. 2nd, the President, Mr. EDWIN LEE, being in the chair.

Mr. BASIL HALL (Bradford) read a paper on the Treatment of Shock by large Doses of Strychnine. He related briefly a case of air embolism occurring during operation and also a case of apparently hopeless shock after the removal of an abdominal tumour. In both these cases when death on the table seemed certain, recovery took place after the hypodermic injection of one-third of a grain of strychnine. He also referred to eleven other instances of severe surgical shock where doses varying from one-fifth to one-third of a grain had been injected with satisfactory results and drew attention to the report of a case of snake-poisoning where recovery followed the administration of large doses. In discussing the remarkable tolerance of the drug in conditions of profound shock he compared with it a similar action in the case of alcohol. He urged that strychnine given boldly in such doses as he had indicated was a valuable remedy in surgical shock in its severer forms.

Dr. S. LODGE (Bradford) read notes of a case of Bilateral Paralysis of the Laryngeal Abductors successfully Treated by Removal of the Isthmus of a Bronchocele.

Mr. LITTLEWOOD brought before the society a series of 7 cases of Volvulus treated by Abdominal Section (3 recoveries) on which he had operated during the past three years. Case 1.—The patient, a man, aged sixty-two years, had volvulus of the large intestine involving part of the transverse colon and descending colon and part of the sigmoid flexure. The volvulus was 10 in. in diameter and displaced the heart upwards into the third intercostal space. Operation was performed 5 days after the onset of acute symptoms. Death occurred 30 hours later. Case 2.—A man, aged sixty one years, with volvulus of the cæcum, part of the ascending colon, and part of the ileum. The volvulus was about 5 in. in diameter. Operation was performed 5 days after the acute onset and recovery ensued. Case 3.—A woman, aged fifty-seven years, with volvulus of the sigmoid flexure. Operation was performed 6 days after the acute onset and death took place 40 hours later. Case 4.—A girl, aged eleven years, with volvulus of the sigmoid. Operation was performed about 36 hours after the acute onset. She had general distension with peritonitis and ultimately recovered. Case 5.—A woman, aged thirty-two years, with volvulus of the small intestine about 10 in. in length. Acute symptoms started about 3 weeks after confinement and the operation was performed six days after their onset. There was general peritonitis with stinking blood-stained fluid in the peritoneal cavity. The volvulous portion of the bowel was deeply congested and adherent by soft adhesions to the surrounding intestines. The pelvis was drained, the lower part of the wound was not closed, and the twisted portion of the bowel was brought near the opening. Thirteen days later the volvulus, which had become gangrenous, separated and was removed. Two months later the intestinal fistulæ were closed by separating the parts from the adhesions and suturing the upper and lower portions of the bowel together. The patient made a good recovery and is now quite well, having since the operation been delivered of

Digitized by Google

twins. Case 6.—A man, aged fifty-three years, with volvulus of the small intestine involving several feet. Operation was performed five days after the onset of the disease. Death occurred six days later. Case 7.—A man, aged twenty years, with volvulus of the small intestine about 2 ft. in length. There were tuberculous mesenteric glands and adhesion. Three days after onset operation was performed. Death occurred four days later.

Dr. WARDROP GRIFFITH showed a case of Painless Enlargement of the Liver occurring in a man, aged twenty-one years. The enlargement, which was very marked, came on after an attack of acute pneumonia and was unaccompanied by jaundice or loss of flesh. There was very slight ascites, but no other sign of portal obstruction, and there was no alcoholic history. He was improving under iodide of potassium. There was no syphilis.

Mr. LITTLEWOOD showed the following:—1. A man, aged forty-six years, whose Rectum he had removed eight weeks previously and had succeeded in getting primary union between the divided ends of the gut. 2. A man, aged forty-five years, with Carcinoma of the Breast. 3. Abdominal Gestation (fourth year). The thorax of the fœtus was opened immediately after its removal from the body. The fœtal heart continued beating one and a half hours.

The following card specimens were exhibited:—

Dr. WARDROP GRIFFITH: (*a*) A case of Primary Muscular Dystrophy; and (*b*) Specimens from the Post-mortem Room.

Dr. BRONNER (Bradford): (*a*) Microscopic specimen of Carcinoma of the Vocal Cords in a man, aged twenty-eight years, simulating papilloma; and (*b*) Angio-fibroma of the Vocal Cord in a man, aged seventy years, simulating carcinoma.

Dr. CHURTON: (*a*) Syphilitic Pachymeningitis, &c., causing complete aphasia and partial right hemiplegia; (*b*) Post-Influenzal Paraplegia; (*c*) Tuberculous Cerebral Tumour with left Hemiplegia and Complete Blindness; (*d*) Chorea of Two Years' Duration in a man aged sixty years; (*e*) Crossed Paralysis; and (*f*) Displaced (congenital) and Fixed Right Kidney with Pyonephrosis.

Mr. MOYNIHAN: Tuberculosis of the Tunica Vaginalis.

Dr. TREVELYAN: (*a*) A specimen of Polypus removed from the Larynx; and (*b*) a specimen of Rupture of the Lung.

Dr. HELLIER: Scoop for Puerperal Uterus.

Mr. SECKER WALKER: Skiagram showing a piece of Brass in an Eye. Attempts were made to remove the metal but as these failed Mules's operation was performed.

LIVERPOOL MEDICAL INSTITUTION.

The Pathology of Ovarian Tumours.—Exhibition of Specimens.

A MEETING of the pathological and microscopical section of this society was held on Dec. 8th, Mr. F. T. PAUL being in the chair.

Dr. ALEXANDER read a paper on the Pathology of Ovarian Tumours. It was chiefly based upon an accurate examination of all the cases he had operated on during the last two years. He gave a careful description of the naked-eye and microscopical anatomy of all his specimens and illustrated his paper by numerous lantern photographs and microscopic specimens. He had had several cases of ruptured cysts and discussed the causes of rupture. He also showed an excellent specimen of confluent ovarian cyst, one large cyst with two pedicles, one going to each side. He gave a good deal of attention to dermoid cysts and described a unique case in which the fatty and hairy contents of the cyst had become agglutinated and rolled into little pellets, so that when the cyst was opened its cavity was filled with little masses having a striking resemblance to green peas.—Dr. E. T. DAVIES discussed the question of the malignancy of ovarian papillomata.—Mr. PAUL and Dr. GRIMSDALE also discussed the paper and Dr. ALEXANDER replied.

Mr. LARKIN showed, for Dr. NATHAN RAW, a specimen of Double Vagina and Septate Uterus obtained from a woman, aged forty-five years, who died from sarcoma of the lumbar spine. She had had three natural labours, but in none of them did the abnormality seem to have been detected. Nor did it cause her inconvenience in any way. The vaginal septum was thick and fleshy and the two vaginas were of about equal size. There was an os uteri on each side. The uterus was not bicornate but was divided by a thick septum.

Mr. HAWKINS-AMBLER showed a Uterus removed by Vaginal Hysterectomy for Cancer confined to the cervix. The patient was fifty-two years of age and was the subject of diabetes, passing 5 per cent. of sugar. Two days after the operation she had symptoms of diabetic coma which passed off on treatment by alkalies. The sugar disappeared from the urine after the operation and had not since returned. Otherwise recovery was uneventful.

Dr. GRIMSDALE showed a well-marked specimen of Tubercle of the Fallopian Tubes. The microscope showed well-marked tubercles with large giant cells in the mucosa. The patient was a single woman, aged twenty-six years, who attributed her symptoms to taking cold. She had a large swelling in the left lower abdomen which disappeared after seven weeks' treatment in hospital. Three months later a similar swelling appeared on the right side. Abdominal section was performed, the fluid escaped, and the tuberculous tubes were removed. She recovered and reported herself well two years later.

Mr. R. A. BICKERSTETH showed a Squamous-celled Epithelioma of the Upper Jaw which undoubtedly commenced in the antrum.

Mr. THELWALL THOMAS showed an Adenoma of the Testis from a man, aged twenty-seven years. It was really extra-testicular and probably arose in the paradidymis.

Dr. LESLIE ROBERTS showed specimens of Giant Bacilli (horn-cell organisms). They were flask-shaped and of no pathogenic significance, growing saprophytically in the horny epidermis.

Mr. R. W. MURRAY showed an exceedingly interesting and rare specimen of Solitary Sacral Kidney. It was obtained from a boy, aged eight years. There was no trace of kidney in the normal position on either side. The single kidney was large and situated below the bifurcation of the aorta on the promontory and in the hollow of the sacrum and more to the left than to the right of the median line. There was a single—left—ureter which was only 2 in. long. The vascular supply was derived from the aorta by two vessels given off at the point of bifurcation and after a short course entering the top of the kidney. Clinically the case was also of great interest. The boy had been passing calculi for three years. On two occasions impacted calculi had been removed from the urethra. Twelve months before death a calculus became impacted in what was thought to be the left ureter, close to the bladder. This Mr. Murray with his finger in the rectum succeeded in forcing into the bladder. A similar impaction occurred some months later which could not be relieved and the region of the left kidney was explored but no kidney could be found. The abdomen was opened and no kidney could be found on either side, but a mass was felt in the pelvis behind the bladder. There was never complete suppression of urine, but the boy died some time later and at the necropsy the true state of the parts was made out. The pelvis of the single kidney was much dilated and the ureter contained numerous calculi.

Mr. DOUGLAS CRAWFORD showed a case of Encysted Hydrocele of the Epididymis. It had formed acutely. The globus major was converted into a large thick-walled cyst containing straw-coloured fluid and having lymph on the walls.

Mr. ROBERT J. HAMILTON showed: 1. A Metastatic Carcinoma of the Eyeball from a woman, aged thirty-five years, who had been operated on six years ago for mammary cancer and again six months ago for recurrence in the axilla. She had had great pain in the eye and gradual loss of vision. The ophthalmoscope showed what appeared to be complete detachment of the retina. 2. A Melanotic Sarcoma of the Choroid from a woman, aged twenty-five years.—A discussion followed in which Mr. PAUL, Dr. ALEXANDER, Mr. RUSHTON PARKER, Mr. HAWKINS-AMBLER, Dr. GRIMSDALE, and Mr. R. A. BICKERSTETH took part.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—Pulmonary Regurgitation.—Sulphonal Poisoning.

THE second ordinary meeting of this society was held on Dec. 7th, Sir JOHN BATTY TUKE being in the chair.

Digitized by Google

Dr. RAINY showed a patient who suffered from Probable Muscular Dystrophy. The affection first showed itself nine months previously, beginning with stiffness and pain in the muscles and joints of the right arm. The arm became thinner and now he was unable to straighten it at the elbow. Certain of the muscles of the upper arm were markedly atrophied. This atrophy showed itself to a much less degree in the forearm. The triceps, deltoid, and spinatus muscles were greatly wasted. There was, however, no increase in the muscular irritability and electrical reaction was normal; there was no trace of degenerative reaction. The case was one of either primary myopathy or a degeneration in the muscles secondary to joint affection.

Mr. STILES exhibited a Child six months after Reduction of a Congenital Dislocation of the Hip by the method of Lorenz. The patient, aged four years, was shown to the society six months previously and Mr. Stiles thought it would be a suitable case for trying this method of reduction which was largely practised on the continent. Lorenz had performed reduction in upwards of 100 cases successfully and another observer had done the same operation 104 times with 97 successes. Mr. Stiles failed in his first attempt to reduce the dislocation in this patient as he did not employ sufficient force. It was essential to pull down the trochanter until it assumed its normal level. After this attempt the child was kept in bed for six weeks with a 12 lb. extension weight applied to the limb. Under chloroform the second manipulation was successful. The child was placed on a mattress on the floor and chloroform narcosis produced. Extension was made by pulling on the limb above the knee-joint and counter extension by means of a perineal band. The force required was considerable and it must be exercised slowly and gradually increased. When the trochanter regained its normal level the thigh was flexed at right angles to the trunk still keeping the limb extended. It was then rotated slightly inwards; when the limb was in this position it was slowly abducted until the limb was at right angles to the trunk, when a sudden sound of reduction was audible and the limb now retained that peculiar abducted position. The limb was now put up in plaster extending above the pelvis and as low as the knee and kept so for six weeks or two months. The bandages were then removed and the amount of abduction having been slightly reduced they were re-applied. The child was now encouraged to walk and so pressure was applied to the rudimentary acetabulum by putting in a high heel on the sound limb. Six weeks later the bandages were removed and the abduction was still further reduced, and again the plaster was renewed. After the third change the child was sent home. Now six months after the reduction there is no deformity, the gluteal folds are symmetrical, there is no shortening of the limb, and the trochanter occupies its normal level. Reduction should be practised early in life—probably about the third year was the best period. It was seldom that the deformity could be removed if the child was above five years of age.

Mr. CATHCART showed a patient in whom symptoms of Myxœdema were subsiding after the left half of an enlarged thyroid had been removed. The patient was a woman who twenty years previously had suffered from somewhat similar symptoms. These disappeared, however, to return eight years ago. There was great alteration in her features; she became heavy and dull; there was swelling of the face, the skin was dry, the tongue was large, the nails were brittle, the hands broadened, and hair fell out. Altogether the symptoms and signs resembled those of myxœdema. The left half of the thyroid was removed three weeks ago by Kocher's method on account of dyspnœa and dysphagia. Since then she had made a remarkable improvement; within a week of the operation she could speak distinctly. Evidently the removal of the left lobe had stimulated the right lobe to a better action. The microscopical sections of the thyroid showed simply a colloid degeneration.

Dr. WILLIAM RUSSELL described the Clinical Symptoms of a case and showed the Brain from which a tumour which caused a breach between the visual word centre and the motor speech centres was removed three times in succession. He indicated the steps by which he had determined that the tumour came to or near the surface in the lower part of the ascending parietal convolution. The tumour was a glioma.—Mr. COTTERILL described the operation as he performed it in this case. The trephine opening exactly localised the tumour which was at first of the size of a walnut. It was removed and the relief to pain was very great. Thirteen weeks later the tumour which had regrown was again removed by means of a periosteal scraper. At this second operation the tumour was of the size of a small Tangerine orange. Again the pain was greatly improved. The third operation was performed when the patient's case was hopeless and was done only to ameliorate her condition.

Mr. STILES exhibited several bones from the body of a rickety child showing Multiple Fractures and skiagraphic representations of the body. The child when admitted to the hospital was in a neglected and emaciated condition with several bed-sores and deformities in the extremities.

Dr. SCOT SKIRVING showed: 1. Extreme Enlargement of the Ischial bursa which occurred in a middle-aged man. 2. The Peculiar Contents of the same—large, rounded, melon-seed-like bodies. The sac contained about 4 oz. of fluid and the cavity was so large that the fist could easily be introduced. Six years previously the patient had suffered from a similar swelling on the opposite side. 3. Ruptured Kidney. The peculiarity in the case was the enormous amount of blood extravasated and the length of time which the man survived—about 12 hours—after receipt of the injury. The patient, a carter, was attempting to climb on to his cart when he fell and was pushed along by the wheel which did not pass over him. He was greatly collapsed but never lost consciousness. The eighth to the eleventh ribs were fractured on the right side and the kidney was entirely broken across on that side, the lower fragment being entirely separated by blood-clot from the upper. Several pints of blood were effused behind the peritoneum. There was also a rupture of the liver, a piece 4 in. long and 1 in. deep being entirely detached.

Mr. CATHCART showed: 1. Microscopic specimens from the Enlarged Left Lobe of the Thyroid removed from the patient whom he exhibited. 2. A piece of Intestine Six Months after Excision and Suture for Gangrene from Strangulated Hernia.

Dr. F. D. BOYD read a paper on Pulmonary Regurgitation. He remarked on the rarity of the affection and described two cases which had come under his observation. One of the cases was evidently due to subacute endocarditis and was treated with benefit by injections of anti-streptococcic serum. Six months later, however, the heart was found to have undergone greater dilatation, the diastolic murmur in the pulmonary area was louder, and the patient gradually sank. The bacteriological examination of the blood proved negative but the injections certainly did good. As regards the causes of this affection it might arise, when not congenital, from secondary dilatation due to increased pressure or from inflammation of the valves. As a rule the mitral valve was the one first affected. Age seemed to be of little importance, and though it was usual in the young one case was described as occurring in a patient aged forty-eight years. The prognosis was grave when once the disease was established, there being a rapid loss of compensation, the right ventricle and the tricuspid valve being both feeble. The diagnosis was not easy. In the two cases described there was no increased loudness in the murmur during expiration as had been said to occur. The murmur might be heard at the back at the angle of the left scapula, but no great importance could be placed in this sign. There was nothing characteristic in the pulse, which was generally rapid, weak, and probably irregular. It was of importance to locate its maximum intensity area and to note its conduction down the left side of the sternum and towards the left.—Dr. GIBSON, Dr. RUSSELL, Dr. RITCHIE, Dr. RONALDSON and Dr. WATSON took part in the discussion and Dr. BOYD replied.

Dr. LOVELL GULLAND contributed a paper on Sulphonal Poisoning. He related the case of a man, aged thirty-nine years, of alcoholic temperament, whose case had come under his personal observation. Owing to insomnia this patient had been in the habit of taking 30 gr. of sulphonal nightly. In all he had taken above 1200 gr. A week before his death his gait was observed to be staggering and his speech was thick, but this was put down to alcoholism. When seen by Dr. Gulland for the first time he was stupid and sleepy though easy to rouse and intelligent when spoken to. His motor power was greatly enfeebled and he could not articulate properly. The urine was deep claret coloured. He died suddenly and the post-mortem examination showed that the liver was chocolate coloured, the kidneys were not cirrhotic but congested, the spleen was diffluent, the walls of the heart were very fatty, the blood was chocolate-coloured, and the brain was congested. Microscopically the liver showed no great change but fatty infiltration at the periphery of the lobules and hyaline degeneration of the

Digitized by Google

walls of the portal vein. In the kidneys the secreting epithelium was only affected, the cells being shrunken into masses of granular protoplasm; the spleen was full of "shadow corpuscles" and the suprarenal capsules showed some columns in which the cells were small and shrivelled. The blood showed poikilocytosis. As regards the clinical symptoms coördination might be affected for weeks by the administration of a single dose. In chronic poisoning gastro-intestinal symptoms generally first appeared, nervous symptoms then appeared, ataxia, paralysis of the facial muscles, general convulsions, coma, &c. The urine contained hæmato-porphyrin as well as unchanged sulphonal. The case usually ended by heart failure. In acute cases the symptoms might come on suddenly; the sleep might be for days; hæmato-porphyrinuria seldom occured in such cases. The prognosis was, as a rule, good in acute but not so in chronic cases. Sulphonal was not readily soluble and so might remain in the intestinal canal or in the blood for long, as it was not easily excreted by the kidneys. The constipation which was usually present would assist in this accumulation. Sulphonal might cause death without producing hæmato-porphyrinuria. This pigment might be present in the urine in cases of lead poisoning or in hæmorrhage from the intestine. The cause of death was probably due to uræmia (using the term in its widest sense). In acute cases as the poison was slowly absorbed the stomach should be emptied at once and a purgative given. The kidneys should be encouraged to act freely. Large enemata of warm water had been found useful. In chronic cases the same remedies might be employed as well as large doses of alkalies to render the urine alkaline and so stop the formation of hæmato-porphyrin. Dr. Gulland has found that more sulphonal was used than any other drug. He pointed out the cases suitable and unsuitable for its administration. The maximum daily dose for a man should be from 15 to 30 grains. It ought never to be given in tabloid form. Hot alcohol (as whisky toddy) was the best vehicle for it. Patients ought to be kept under observation during the whole time the drug was being taken. Sulphonal should be used with much greater caution than was usual at present.—Sir JOHN BATTY TUKE, Dr. CRAIG, and Dr. RUSSELL made remarks on the use of the drug.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The usual monthly meeting of this society was held at 40, Leicester-square, W.C., on Dec. 5th, the President, Mr. J. Fairbank, being in the chair.—Mr. Storer Bennett, the curator, showed a Denture of a somewhat primitive character which had been made in Naples in 1850. The plate was lined with wash-leather and was tolerated by the patient for nearly twenty years.—Mr. J. F. Colyer showed for Mr. Carter of Leeds a Suture Case for use in the treatment of fractured mandibles.—Mr. R. H. Woodhouse and Mr. Clayton Woodhouse exhibited Models of Cases in which Irregularities in the Position of the Teeth had been corrected by extraction.—Mr. W. A. Hunt brought under the notice of the members a patient in whom the mandibular teeth had been removed and the alveolar ridge had almost disappeared so as to have practically a flat surface. He asked for suggestions as to the mode by which a satisfactory denture could be made.—Mr. F. J. Bennett read an interesting paper on "Some Old and New Views of Calcification of the Teeth." The researches of Rainey and Harting which have so largely influenced ideas on the calcification of teeth and bone were referred to. Their experiments, it will be remembered, consisted in causing salts of lime to be formed in the presence of a viscid medium. The substances employed by Harting were either calcium chloride, calcium nitrate, or calcium acetate, uniting in the solution with either sodium carbonate, sodium phosphate, or ammonium phosphate. The colloid fluid employed was albumin or gelatin. The experiments of Rainey were made with gum arabic in solution which was allowed to mix slowly with another solution of gum containing potassium carbonate, the calcium in the gum arabic combining with the carbonate from the potash to form calcium carbonate which after a lapse of some weeks was found not to exist in crystal form but in the shape of globules. The union of these globules exactly resembled the youngest layers of the shell of crustaceans and he assumed that these globules also explained the nature of interglobular dentine. Mr. Bennett considered that a theory of calcification of bone and dentine based on these experiments was open to grave objections. Calcium phosphate formed from calcium chloride and sodium or ammonium phosphate in the presence of albumin or gelatin appears in the form of crystals. If calcium carbonate is produced at the same time the precipitate consists of the organic matter plus two calcareous salts. If calcium phosphate exists in large quantity the precipitate remains, even after several weeks, in the amorphous or colloid state, but if the calcium phosphate is present in small quantity then the precipitate is in the form of calcospherites. In 100 parts of enamel there are 89·82 per cent. of calcium phosphate and 4·38 per cent. of calcium carbonate, while in dentine the calcium phosphate amounts to 56·7 per cent. and the carbonate to 3·36 per cent.; it is therefore difficult with this overwhelming proportion of calcium phosphate to assume that calcospherites occur in connexion with tooth calcification. Experiments of Dr. Ord confirm this view and it is therefore evident, if the idea be entertained that interglobular dentine is allied to Rainey's calcospherites, it can only be so on the assumption that the defective area consists principally of carbonate and not phosphate of lime and on this point there is no evidence. The spherical forms met with in the various stages of tooth formation are not easy to account for and it is by inference only that they are connected with the globules or calcospherites of Rainey and Harting. A reference was made to Dr. Sims Woodhead's views on bone formation which tend rather to the idea that the salts are deposited in the fibrous matrix simply as granular particles in no chemical relation with the bases whatever and Mr. Bennett considered that in the theory of Dr. Woodhead there may be found a clearer understanding of tooth formation.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 1st at 20, Hanover-square. The President, Dr. R. Fortescue Fox was in the chair.—Dr. William Bruce read a paper on Separate Rôles played in Rheumatic Affections by (1) the Joints; (2) the Muscles; and (3) the Nerves; and the Consequent Indications for Treatment by (1) Rest; (2) Baths and Massage; and (3) by Electricity. With regard to the nerves he stated that particular regions are chosen, as it were, for the expression of pain and those regions in a general way correspond with reflections in particular sensory tracts of the brain and spinal cord. He regarded acute rheumatism as a distinct "zymotic" disease. After an experience of nearly thirty years in the treatment of rheumatic affections of hip, ankle, and thumb, and the corresponding joints of the lower limb, he held that the diseases are really articular and that neuritis is the result and not the cause of the mischief.—The President pointed out the present disadvantage in discussing rheumatism inseparable from the want of clear definition in the terms used. It was difficult to believe that all rheumatic pains in the muscles and nerves were due to primary affections of the joints.—Dr. Geo. Oliver said he had long entertained the view that in chronic rheumatism and chronic goutiness the state of the nerve centres played an important rôle in causation. But there were difficulties in accepting the nerve origin as the sole one. For some years he had been studying the blood-pressure and the blood in these cases and he had come to the conclusion that viewed from these standpoints there was no line of demarcation between chronic rheumatism and goutiness. He therefore regarded these conditions as clinically indistinguishable.—Dr. Bruce replied.—Dr. R. W. Felkin read a paper on the Climate of the Egyptian Soudan. He began by mentioning the size of the country and explained that in such a vast area various climates must be obtained. Roughly speaking, the ninth degree of N. latitude divided the country into two parts. To the north of it are deserts, rocks, an Arab population, a high mean annual temperature (over 85° F.), a dry atmosphere, and slight rainfall (under 5 in. north of Dongola, under 10 in. north of the Sobat). South of 9° N. the country was very fertile, it had a high mean temperature of about 75° F., the range of temperature was slight (about 10° F.) and the humidity was over 70 per cent. This area is inhabited by negroes. He concluded by referring to the prevalent diseases—malaria, dysentery, diarrhœa, Guinea-worm, &c. He said that it was noteworthy that malaria and phthisis did not occur together in Central Africa and he mentioned some interesting results which he had obtained with tuberculin in malaria. Dr. Felkin urged the importance of the right men being sent to open up the country and gave his opinion as to the kind of men best fitted for life in tropical Africa.—The President said

Digitized by Google

that it behoved the British Balneological and Climatological Society to consider not only the curative or medical value attaching to particular climates but also in what manner different climates affected healthy populations. This latter view applied especially to our colonies and dependencies and became of great importance in times of national expansion like the present.—After various remarks and questions from members present Dr. Felkin replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society on Dec. 7th, Mr. T. D. Pryce, President, being in the chair, Mr. Laws read a paper on Pseudo-renal Retinitis, giving notes of cases illustrated by drawings showing that all the appearances of renal retinitis might be present where there was no evidence of renal disease. In all these cases the retinal arteries were of the "silver wire" type of Mr. Gunn, and it was suggested that there was in these patients a similar condition of the renal arterioles, causing interference with excretion and an augmented proportion of waste products in the blood. This increase was not more than might be tolerated, for many of these patients lived in good health for years. But when there was added to it a circulatory difficulty such as that due to the pressure of the thickened retinal arteries on the veins the tissues succumbed to the poison and a renal retinitis was produced.—Mr. Anderson showed a woman after Choledolithotrity performed on Oct. 17th. The patient had suffered for a lengthened period from frequent attacks of slight jaundice, with severe pain radiating over a wide area in the thorax and abdomen and terminating in vomiting which at once relieved the pain. There was marked cachexia and emaciation. The single soft stone, ½ in. in diameter, lay in the diverticulum of Vater and when discovered was easily crushed between the fingers. The patient has since been quite well and has gained 16 lb. in weight.—Mr. Willis referred to a precisely similar case under his own observation, which was operated upon in the same manner thirteen months previously with complete relief up to the present time.—Mr. Mackay showed a Dermoid Cyst removed from the broad ligament of a girl aged eleven years.

ERRATUM.—Pathological Society.—In the report of the meeting of this society published in our issue of Dec. 10th the name of Mr. J. R. Lord was by an error printed as Mr. J. R. Lunn.

Reviews and Notices of Books.

Atlas der Syphilis und Syphilisähnlichen Hautkrankheiten. Für Studirende und Aerzte. Von Dr. MARTIN CHOTZEN. (*Atlas of Syphilis and Diseases of the Skin resembling Syphilis.* For Students and Practitioners. By Dr. MARTIN CHOTZEN.) Hamburg and Leipzig: Leopold Voss. 1898. Price, bound in morocco, 40 marks.

WE have received the seventh and eighth and the eleventh and twelfth parts of this atlas. The other numbers are not to hand. There are in all seventy-three plates, coloured and uncoloured, representing not only syphilitic lesions but skin diseases supposed to resemble them. Of these latter, counting from the index, there appear to be fully one-half. These, while perhaps adding to the value of the atlas to the general practitioner, detract from it as a work of reference for syphilitic affections, with which we should have thought there would be no difficulty in filling the entire book, the more so as they are not confined to surface lesions. Moreover, we do not think that the author has been always wise in the selection of the non-syphilitic affections, as in many instances they are not those most likely to be confused with syphilis. Confining our attention to the parts before us we find in Part VII. a papulo-squamous syphilide, two of leucoderma colli, a papulo-circinate eruption of the neck not very well drawn, a papulo-pustular eruption of the forehead, and two small figures, a framboesiform syphilide of the cheek, nose, and penis, and a bromide acne of the thorax which is not a characteristic eruption. The syphilides, except the one mentioned, are good representations. In Part VIII. there is a poor plate of acne vulgaris of the back, a worse one of extensive impetigo contagiosa of the face, a well-drawn tubero-serpiginous syphilide of the back, a very peculiar-looking serpiginous tubero-ulcerous syphilide, a good tuberculo-serpiginous lupus vulgaris of the buttock, and an unrecognisable psoriasis vulgaris of the scalp.

The plates in Part XI. give in colour good representations of stomatitis mercurialis and paronychia and onychia exulcerans, defluvium capillitii from a papulo-squamous syphilide, alopecia areata—not the most typical form—and periostitis of the leg bones. The uncoloured are five figures representing perforation of the hard and soft palate, suppurative periostitis of the bones of the nose, and two figures of defective septum. Part XII. represents in colour serpiginous ulceration of the head and forehead with a node—not a very good example. A plate with six figures of lesions of the larynx and eye is well executed; a hand labelled "lues hereditaria, pemphigus syphiliticus" is, although a well represented, not a well-selected, example of the affection. Among the uncoloured there are again two examples of the "lost chord" in the bridge of the nose, a very good reproduction of cicatrices periorales in hereditary syphilis, another of the Hutchinsonian teeth, and a skiagraph of nodes in the leg bones.

Although the size of the atlas is quarto the plates themselves are about 7 in. × 5 in. and the lesions therefore are only life size when a small portion is represented. The reproduction is apparently by a photo-lithographic process, and though not of the highest class of coloured plates is sufficiently effective. The defects appear to be due rather to the artist and the author's selection of cases than to the publisher's portion of the task. As a whole, the ordinary skin lesions are not very successful and some of the syphilitic lesions might have been taken from better selected cases. Still, considering the moderate price of the work and the large number of plates, the practitioner will receive an adequate return for his outlay.

Doctor Therne. By H. RIDER HAGGARD. London: Longmans, Green, and Co. 1898. Price 3*s.* 6*d.*

THE youngsters who are popularly supposed to devour each new novel by Mr. Rider Haggard will hardly accept "Doctor Therne" as a welcome addition to the school library. This grim story is intended to stimulate the unintelligent and to enlighten the uneducated parents who are ready to gamble with the lives of their children and neighbours by taking advantage of the "conscientious objection" clause of the new Vaccination Act. Since a Norwegian dramatist converted his critics by proving that a stirring and romantic play can be woven round the defective drainage of a provincial town we have come to realise that no subject is common or unclean to the artist any more than to the man of science. Still it must be admitted that vaccination does not sound a tempting theme for those who seek oblivion in the perusal of stories. But here is where Mr. Haggard's skill is most markedly shown. His didactic treatise is also an excellent novel.

There are many who think Mr. Haggard's transpontine taste for bloodshed does more credit to the heart of an Imperial Federationist than to the head of a talented novelist, and with these it has been a subject of lament that the author of "Jess"—a keen observer and a penetrating critic of modern life—should have directed his skill towards the delineation of the operatic parts and unconvincing thaumaturgy so dear to his younger admirers. But if in the earlier pages of "Doctor Therne" there is some of the old leaven—a needless adventure with Mexican brigands, a precipice, and those scenic properties which suggest an

Digitized by Google

Alhambra ballet—we are soon carried into a more realistic atmosphere. A certain Dr. Therne sets up a practice in the city of Durnchester, and by his skilful treatment of both surgical and medical cases has the misfortune to collide with the long-vested interests of the distinguished local physician, Sir John Bell. Honourable rivalry soon degenerates into open enmity when Dr. Therne has the misfortune to correct the wrong diagnosis of the older and more experienced man. When Dr. Therne's wife falls ill, in order to smooth matters over he calls in his enemy for the accouchment. The wife, partly owing to Bell's clumsiness, develops puerperal fever—a fact concealed from Dr. Therne, who is permitted to carry to his own patients the infection from his wife's sick-room. Both the wife and a distinguished patient of the unfortunate Dr. Therne succumb to the malady thus unhappily disseminated. A verdict of "manslaughter" at a coroner's inquest, though followed by subsequent acquittal at the assizes, entirely ruins Dr. Therne, and Sir John Bell's practice is triumphantly re-established—a sufficiently revolting (and we hasten to add highly improbable) picture of the amenities of medical men towards each other. A new character a real creation or, let us say, a real portrait of which Mr. Haggard may be proud now appears—one Stephen Strong, an honest, stupid, rich, wrong-headed tradesman, faddist and anti-vaccinationist. The sketch of this man's home; of the wife suffering from lupus attributed to infected vaccine lymph; of the idiotic conversation of the couple who, by a peculiarly happy touch to our thinking, are shown as firm believers in Anglo-Israelism—all this is done in a slight but masterly fashion. Strong espouses the cause of Dr. Therne as a persecuted man.

By a cleverly imagined series of fortuitous circumstances, by offers of money and by the prospect of regaining a practice Dr. Therne is now tempted to lend his name and the weight of his experience to the cause of anti-vaccination in the face of his knowledge and deep-rooted convictions as to the efficacy of vaccine lymph as a prophylactic against small-pox. In rapid narrative an election to Parliament, the ravages of a small-pox epidemic at Durnchester and the moral and psychological decadence of Dr. Therne are crowded into what might have been a much larger book. Few sensational scenes in all fiction—we say this quite deliberately—have been better told than where the daughter of the miserable hero discovers her father vaccinating himself at midnight after a long meeting in favour of the "conscientious objector" clause. The final exposure of Dr. Therne on a public platform by a young medical man who makes him show his arm to a crowded meeting is also a thoroughly well-described episode, and was probably prompted by an occurrence which recently took place in London in connexion with the adventures of a gentleman whose career would have had the deepest interest for Mr. Haggard a few years ago.

Mr. Rider Haggard has now entered into an honourable competition with Ibsen and Zola who have not disdained to lend their eloquence to curing the deafness and blindness of the stupid, the ignorant, and the mischievous for whom blue-books and statistics are vain things fondly invented. Dr. Therne will certainly challenge comparison with Dr. Stockmann, in the "Enemy of the People." In the former we find a man sacrificing honour and character and morals, posing as the friend of society for material advantage, a course which is only palliated by the cruel conspiracy and the more cruel temptations which beset him. In Dr. Stockmann we see an attractive and heroic instance of a man sacrificing all worldly wealth, his family, his home, and his reputation in the cause of truth and honesty, and deliberately choosing to be regarded as the enemy of society by his fellow citizens while discharging what he conceives to be his duty. To our mind Mr. Haggard would have shown subtler art had he decided to present not a weak man whose wrongs excuse him so much, but a man who from deliberate fraud at last came to believe in his own perversion, and who would deceive others being himself deceived. Dr. Therne is just a trifle too romantic for his sordid sin. His antithesis, Dr. Stockmann, was none the less sympathetic for being rather ridiculous, rather irritating, and therefore more probable. However, we do not want to wear the appearance of teaching Mr. Haggard to write a story.

In conclusion we must commend Mr. Haggard's courage in thus entering the lists against the anti-vaccination party. As a novelist and a politician alike it is evidently to his advantage to take no step that would be likely to alienate from him any large body of possible supporters. Yet he has risked losing many readers and creating a fanatical opposition to whatever he may do in public or private capacity for the sake of telling the truth.

Jahresbericht über die Fortschritte auf dem Gebiete der Chirurgie. Redigirt und herausgegeben von Professor Dr. HILDEBRAND in Berlin. II. Jahrgang: Bericht über das Jahr 1896. (*Year-book of Surgery.* Edited by Professor HILDEBRAND of Berlin. Second Year: Report of the Year 1896.) Wiesbaden: J. F. Bergmann. 1897. Pp. 1341.

THIS enormous volume represents without doubt an immense amount of work. Professor Hildebrand has been assisted by a large number of surgeons, chiefly in Germany, but also in other countries, and they have collected here references to all books and papers on surgical subjects which appeared during 1896; but there are more than references in many cases: whenever a paper has appeared to be of much importance an abstract of it is given, of a length quite sufficient to enable the reader to appreciate the value of the paper. A very convenient system of classification has been adopted. In the first section is given a list of articles referring to the history of surgery, and then are catalogued all the general treatises on surgery which were published during the year. Next comes a list of hospital reports, followed by the papers connected with topographical anatomy. In each case a summary is given of those papers which are considered to deserve it. For instance, a whole page is devoted to a *précis* of an article by Dr. Plummer on the Surgical Anatomy of the Middle Meningeal Artery which appeared in the "Annals of Surgery." General Surgery comes next and then the several parts of the body are dealt with in turn. An Index of Authors is given and it occupies nineteen pages and there is also an Index of Subjects of equal length. We have not been able to detect any omissions, though of course there may be some, and many English names are misspelt; but taking the work all in all it would be unreasonable to expect a more complete or more usefully arranged book. Such works of reference as this are imperatively demanded nowadays by all who have to work in any department of science, for it is not possible for anyone to keep *au courant* with all the numerous papers and articles which pour out from the scientific publishing houses. We can only hope that this "Jahresbericht" will continue to appear regularly.

On Deafness, Giddiness, and Noises in the Head. By EDWARD WOAKES, M.D. Lond., Senior Aural Surgeon, London Hospital, Lecturer on Diseases of the Ear, London Hospital Medical College; assisted by CLAUD WOAKES, M.R.C.S. Eng., L.R.C.P. Lond., Assistant Surgeon to the London Throat Hospital. Fourth edition. London: H. K. Lewis. 1896. Pp. 224, 8vo. Price 10*s.* 6*d.*

TWELVE years have elapsed since the publication of the third edition of this book and it has been found necessary to rewrite the work almost entirely. The main idea is the

Digitized by Google

ame as that which pervaded the book when it first appeared. It is that in the body there are "correlated tissue areas"; between any two areas thus correlated an intimate relation exists, so that any departure of one of them from its ordinary state is immediately appreciated by a corresponding set of nutritive changes in the other. These regions may be often widely separated, and the explanation of their mutual interdependence is to be found in the association of their afferent and efferent nerves with a sympathetic ganglion. This volume deals, as its title states, with several important aural symptoms, and endeavours to show that in great part they are explicable as reflex phenomena from the irritation of areas which are "correlated" with portions of the auditory apparatus. The treatment to be followed in patients suffering from these symptoms is very fully discussed. Chapters on Foreign Bodies in the Ear, on Ear Affections in Infancy and Childhood, and on Post-nasal Growths are also given. Without assenting to all the propositions advanced by the authors we may say that many parts of the book are very suggestive and well worthy of perusal by those who have to deal with the morbid phenomena associated with the auditory apparatus.

LIBRARY TABLE.

The New Sydenham Society's Lexicon of Medicine and the Allied Sciences. Part XXIV. Scap–Tape. London: H. K. Lewis. 1898.—We have just received Part XXIV. of this valuable lexicon which is now carried as far as "Tape-grass." The society's annual report states that it is confidently hoped that the lexicon may be completed within twelve months and that considerable progress has been made with a Supplement which will follow the completion of the main work. The editors, Mr. Henry Power and Dr. Sedgwick, may be congratulated on this approaching termination of their labours, and many of our readers will no doubt be glad to have in their hands the final number of an excellent work of reference, Part I. of which appeared in 1878

Materia Medica, Pharmacy, Pharmacology, and Therapeutics. By W. HALE WHITE, M.D., F.R.C.P. Lond. Third edition. London: J. & A. Churchill. 1898. Price 7*s.* 6*d.*—The third edition of this well-known text-book scarcely calls for detailed consideration. The chief features of the book are retained while the author has brought the information up to date, more particularly by bringing it into harmony with the new British Pharmacopœia. He includes a list of the additions, together with a list of the omissions. The author has contrived to pack a large amount of information into a very small space and it is presented in a form which can be readily assimilated. He includes in this edition a consideration of diphtheria antitoxin, streptococcus antitoxin, and tetanus antitoxin, the last being dismissed in four lines. These are followed by five lines on anti-venomous serum and by short descriptions of hydrophobia antidote and of piperazin which seem rather misplaced after the description of serums and antitoxins. To the short list of *errata* should be added "aconita" (p. 11) for "aconitina."

Catechism Series. Surgery: Part II., pp. 63; Part III., pp. 64; Part IV., pp. 64; Part V., pp. 64. Anatomy: Part II., Head and Neck. Second edition, with Plates. Pp. 72. Edinburgh: E. and S. Livingstone. Price 1*s.* each net.—There is a natural tendency amongst students as the day of examination draws unpleasantly nigh to seek the aid of "cram" books of one kind or another, and provided that they have done their work well they may derive no little benefit from studying a *résumé* of the subject and from having the facts put before them in a new way, but if a student who has utterly neglected his work expects to gain the required knowledge in a week or two by reading a small volume he will utterly and deservedly fail. These volumes are, as "cram" books go, very fair and if used intelligently may be found of much value. A number of diagrams are given, most of them borrowed from M'Lachlan's "Applied Anatomy," and they are likely to prove helpful.

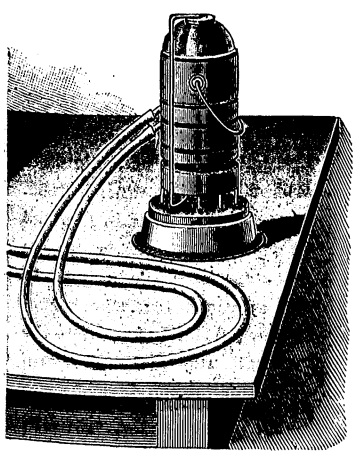
Nine Medical Songs. Words by J. BLUMFIELD, G. H. RANSOME, and F. H. Music by C. N. CHADBORNE. The Librarian, St. George's Hospital. Price 2*s.* 6*d.*—Most of these songs, though primarily written for St. George's men, would be welcome at any medical smoking concert, for the only two purely local ones are "Back to the Corner Again" and "A Song of St. George's." One of the best, though possibly not the most taking, in the sense that it would not be yelled in full chorus at the end of an evening with so much zest as the "Song of St. George's" is "The Lament of the Large White Kidney." The dignified pathos of this is most touching and Mr. Chadborne's music is in every way worthy of the words. If he were to orchestrate it the piece would produce a most striking effect at a hospital concert. The introduction given out by three trombones, except bars four, five, and eight which should be allotted to that impassive yet sorrowful instrument the bass clarionet, would bring tears to the eyes of even the most hardened pathologist. The first number, "Oh, would I were a surgeon," is an admirable example of F. H.'s skill in writing incisive lyrics, and the music has an unmistakeable and possibly intentional flavour of a passage from "Honour and Arms." Altogether we congratulate St. George's and must in addition praise the designer of the cover.

Health in the Nursery. By HENRY ASHBY, M.D., F.R.C.P. Lond. London: Longmans, Green and Co. 1898. Pp. 227. Price 3*s.* 6*d.*—This is a very well-intentioned little book, written by one fully equipped by his experience to deal satisfactorily with the subject. While dealing chiefly with the prevention of disease the author does not hesitate to indicate the serious results which may follow when Nature's laws are broken. It is essentially a book of health in infancy and early childhood. The author wages warfare against ignorant customs and prejudices which have become sacred through long descent. Nothing connected with the surroundings of infancy appears to escape him. He deals with early training, with the furniture of the nursery, with the hygiene of infancy and childhood, under which term he includes a consideration of the care of infants prematurely born; then he passes on to deal with the clothing appropriate for the various ages, and in subsequent chapters he treats of dentition, of the early signs of disease, of the mental development of the infant, and of backward and exceptional children. As in all other books of this type much space is devoted to a consideration of the dietary of the infant. Concerning the artificial feeding of infants the information given will be most helpful to mothers since it is both simple and practical and it is commendably free from the advertisements of patent foods or of patent forms of milk which are so frequently to be found under such a heading. Greater emphasis might perhaps have been laid on the dangers of a dietary rich in farinaceous food during the early life of the infant. It would also perhaps have been more in accordance with custom to use the term anterior fontanelle in contradistinction to posterior fontanelle instead of employing the term superior fontanelle. The chapter on the early signs of disease is likely to be extremely serviceable and, in fact, the directions throughout the book are calculated to encourage habits of observation and common sense rather than to induce those entrusted with the care of a child to think that they can, unaided by the medical profession, safely tide over all dangers. The book is brightly written and the illustrations, although scarcely artistic, are sufficient to serve their purpose. One of the problems which remains unanswered after the perusal of this book is: Why do

Digitized by Google

authors of popular works concerning babies so constantly drop into poetry?

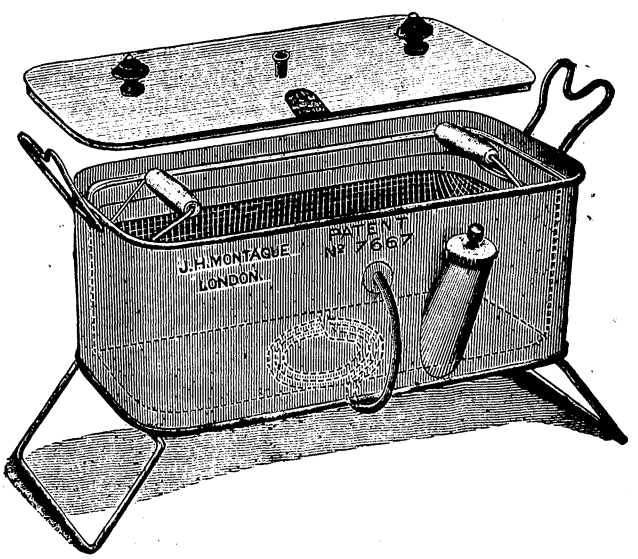
JOURNALS AND REVIEWS.



The Practitioner.—The opening editorial paragraphs of the December number announce that in future this periodical will be enlarged and the subscription will be increased to one guinea per annum. The editor refers in feeling terms to the retirement of Dr. J. F. Goodhart and Mr. Treves from hospital work and advocates the inauguration of a state of things in England comparable to that of the German clinics, where the seniors have a staff of well-trained assistants to take routine work off their hands. Mr. Alfred Willett reports a case of Axillary Traumatic Aneurysm which underwent spontaneous cure; among other papers there is one describing that rare condition Primary Sarcoma of the Vagina; the growth was removed and there has been no recurrence for two and a half years. Mr. James Cantlie writes upon Sprue, and Dr. Sydney Short recounts a case of Aneurysm of the Aorta in which pressure symptoms were limited to the trachea. A story by Philip Lafargue, Reviews of Books, the Periscope, Hospital Notes, Notes on Public Health, and the usual pages of Practical Notes make up a good number.

The Phonographic Record. December, 1898. London: Sir I. Pitman and Sons.—This forms the last number of Vol. IV. and is issued with the index to this volume. The opening paper gives an account of an interesting case which came under the observation of Sir William Gowers and which he diagnosed as a case of polyneuritis of obscure toxic origin. The patient did not immediately improve under Sir William Gowers's treatment, but subsequently it was discovered by her medical attendant that she was in the habit of using a hair stimulant containing lead and powdered sulphur. On the lotion being discontinued the patient recovered. Mr. Norman Porritt concludes his Two Instructive Examples of Abdominal Surgery and Dr. Thomas Wilson gives an account of Transient Spasmodic Torticollis in a case of Intraperitoneal hæmorrhage due to tubal abortion.

New Inventions.



THE "PERFECT" HOT APPLIANCE.

BY means of this apparatus the continuous application of heat, either moist or dry, to various parts of the body, and for numerous purposes, may be conveniently and successfully accomplished. Its essential principle is that water heated in metal cylinders by an automatically regulated alcohol lamp is conveyed by an india-rubber tube to accessory attachments differing in construction according to the purpose for which they are required, and the water after circulating in them returns to the cylinders, where it is heated once more. One of these attachments is a curved metal disc measuring 6 in. by 8 in., to be placed in contact with the abdomen; if wet flannel be interposed between the disc and the skin the effect of a poultice or hot fomentation is obtained without the necessity of disturbing the patient at frequent intervals to renew it, a drawback inseparable from the ordinary poultice. The regulation of the lamp is effected by means of a wire attached to the top of the heating cylinder. We have tested its action and find that it is quite satisfactory. Moreover, it acts perfectly even if the circulation through the tube be stopped. The "Appliance" is 3 in. in diameter by 9 in. high and together with its case it weighs 3 lb. The price is £1 1*s.* and it may be obtained from the "Perfect" Automatic Hot Appliance Co., 303 and 304, Dashwood House, New Broad-street, E.C.

ATMO-THERME STERILISER.

SURGEONS who prefer to use sterile rather than antiseptic dressings will doubtless welcome a steriliser for use in the operating room. The instrument consists of an inner chamber intended for the materials to be sterilised, surrounded by a water jacket heated by a flame placed below. The steam generated in this jacket is conducted through a coil of copper tubing (the super-heater) placed in contact with the flame immediately below the body of the instrument, and is thereby raised to such a temperature as renders it not only quite dry but capable of drying that with which it comes in contact. This dry super-heated steam is then admitted to the inner chamber, where it rapidly penetrates and sterilises any dressings, &c., which may be within. Some preliminary experiments which I made with an instrument placed in my hands by the inventor for the purpose of testing its efficiency, and which was constructed on principles similar to those of the steriliser shown below, were very satisfactory. Non-sporogenous micro-

organisms — viz., bacillus prodigiosus, bacillus typhosus, bacillus diphtheriæ, spirillum choleræ, bacillus coli communis, and staphylococcus pyogenes aureus—were destroyed in ten minutes though they were enclosed within a considerable quantity of rather tightly packed cotton-wool. Dust-covered cotton-wool similarly enclosed was also sterilised in ten minutes. Spores of bacillus subtilis contained on thread, enclosed within a tightly rolled bandage which was itself surrounded by half a pound of cotton-wool, required an exposure of fifteen minutes to effect sterilisation. These results appear at first sight to differ from those of von Esmarch and others as to the disinfecting value of dry super heated steam, but in the apparatus in question it is probable that the material to be sterilised is first exposed to saturated steam and afterwards dried as the temperature rises above 100° C. The instrument used by myself had several minor defects, but I believe these have been remedied in the present instrument. The maker is Mr. J. H. Montague, of 101, New Bond-street, London.

THE LANCET.

LONDON: SATURDAY, DECEMBER 17, 1898.

A SUPPLEMENT to the twenty-seventh annual report of the Local Government Board consisting of the report of the medical officer for the year 1897–98 was issued on Wednesday last, and as usual contains information of the first importance to medical men and practical sanitarians. It is on this occasion, as we have found it on previous occasions, useless to attempt to review exhaustively in one or two editorial articles a stout volume packed with information presented in the most concentrated form, so that we must content ourselves with selecting one or two of the topics dealt with for some extended notice, while with regard to the others we must refer our readers to the report[1] itself. In particular these remarks apply to the auxiliary scientific investigations which constitute an interesting group of appendices. Among these a communication from Dr. KLEIN on the morphology and biology of bacillus enteritidis sporogenes dealing with the association of this microbe with infantile diarrhœa and cholera nostras, as well as its relations with milk, sewage, and various kinds of manure, is sure to attract special attention. Sir RICHARD THORNE in a previous report to the Local Government Board has pointed out that microbes of the anaërobic class have not received from bacteriologists and epidemiologists adequate attention, so that Dr. KLEIN'S appendix is opportune. One story in this appendix—that of a severe outbreak of diarrhœa in St. Bartholomew's Hospital in March last, presents interesting facts in support of the view that a close connexion exists between the bacillus enteritidis sporogenes and diarrhœa. Such evidence is of course only presumptive, but it is none the less forcible, while it supplies excellent reason for perseverance in similar research.

An interesting *communiqué*, in view of previous work by the Local Government Board in the same direction, is a report by Dr. G. S. BUCHANAN on the occurrence of certain cases of enteric fever in the following sanitary districts of Suffolk and Essex—Clacton, Walton-on-the-Naze, Haverhill, Braintree, Lexden and Winstree, and Tendring, and the relations of oyster infection to these cases. Dr. BUCHANAN'S summary of facts shows that in a population of some 16,000 persons distributed among places so far apart as Braintree in the centre of Essex, Clacton on the east coast of this county, and Haverhill in Suffolk about eighteen miles from Cambridge, a total of 29 persons only were heard of as having been attacked by enteric fever between the beginning of June and the end of October, 1897, while of these 29 persons no less than 26 had consumed oysters about a fortnight before the date of their attack — "about a fortnight" being regarded as a fair definition of the incubation period of enteric fever. Stating these facts alternatively Dr. BUCHANAN finds that among the inhabitants of, and visitors to, the more limited area comprising the towns of Clacton-on-Sea, Walton-on-the-Naze, and the parish of St. Osyth (this is a small town in the rural sanitary district of Tendring) the total of persons heard of as having been attacked by enteric fever during the month in question was 26, and all these 26 sufferers had consumed oysters about a fortnight before the onset of illness. To quote Dr. BUCHANAN'S own words, "The improbability that a series of coincidences such as this should have happened by mere accident is obviously very great." The next step in the investigation was to trace the suspected oysters, and here Dr. BUCHANAN supplies evidence with full detail and corroboration to show that the particular molluscs by which the 26 persons came by their infection could in each instance but one be affirmed "almost with certainty" to have come from layings at Brightlingsea. Now, in 1895 Dr. H. T. BULSTRODE, medical inspector to the Local Government Board, visited Brightlingsea in the course of an official investigation into the conditions under which oysters are cultivated and stored along the coast of England and Wales, and in his report[2] gave due warning that Brightlingsea was a rapidly growing town and that the danger of contamination to oysters laid down there must tend to materially increase with the addition of new houses unless steps were taken for the proper disposal of sewage. Later Dr. BULSTRODE drew attention to certain layings as being particularly liable to pollution. Dr. BUCHANAN now shows that of the 25 cases where the implicated oysters could be referred "almost with certainty" to layings in Brightlingsea Creek, in 20 cases the oysters had been taken from one or other of two particular layings situated on the foreshore which had been pointed out by Dr. BULSTRODE as conspicuously exposed to sewage pollution. From all these facts it is obvious to our mind that until the sewage of Brightlingsea is dealt with properly a grave risk attends the consumption of oysters obtained from layings there.

Of the most important sections of Sir RICHARD THORNE'S report, important not only from a topical point of view but on account of their bearing on the public health of the future—we refer to those dealing with the question of vaccination—we say nothing now, for we shall later take opportunities to refer to the various points touched upon in the report in some detail. We quote only Sir RICHARD THORNE'S grave words in announcing the publication of a digest of the vaccination officers' returns for births during 1895. "The number of children," he says, "now born in England and Wales who in one way or another escape vaccination is probably not much less than one-third of the whole. In this way the country is being prepared for wide-spread epidemics of small-pox such as have been unknown to the present generation — unless, indeed, the invariable rush and clamour for immediate vaccination on the part of those who have neglected or declaimed against the operation

Digitized by Google

during times of freedom from small-pox should be capable of being so far met in the moment of emergency as largely to mitigate the impending disaster."

AT the annual meeting of the constituents of the Hospital Sunday Fund held at the Mansion House on Dec. 12th and presided over by the Lord Mayor several subjects of considerable interest were discussed in a way which promises well for the success of the Fund in the coming year. It is now somewhat trite to say that this institution is the most effective of all means for uniting religious men of all creeds. But this argument in favour of the Metropolitan Hospital Sunday Fund was never more happily or effectually used than on Monday by the Bishop of STEPNEY, the Rev. W. H. HARWOOD, and other speakers. The slight falling off in the amount of the Fund for the present year has evidently in no serious degree discouraged the members of the Council. It is recognised that the financial disturbance occasioned by the claims of the Jubilee year could scarcely cease all at once and that those claims sufficiently explain the diminished collection. The Bishop of STEPNEY in his excellent speech made a happy suggestion which we trust will be responded to liberally by the public. He pointed out that the collections of the Fund since its commencement in 1873 have amounted to £952,525 and that the sum necessary to make this into a million is £47,475, only a few thousands more than the ordinary collection. Next year would, he hoped, see the total sum made up to the round £1,000,000. There is nothing unreasonable in believing that the ministers of religion will be able to found on this speech an appeal which will raise the sum of the Fund to the amount desired and suggested by the Bishop of STEPNEY. The tone of the meeting and the hearty interest displayed in the Fund by the new Lord Mayor confirm us in this hopeful view.

Another feature of the meeting of Monday was the strong expression of feeling in favour of the voluntary principle as applied to the hospital system. Canon FLEMING gave very effective utterance to this sentiment. He said he hoped the day would never come when voluntary liberality in support of the sick and wounded would be supplanted by State aid. Canon GRAHAM, representing the Roman Catholics, spoke with equal heartiness in the same sense and said that the voluntary maintenance of hospitals in this country was the envy of all foreigners. It is gratifying to find that there is no abatement amongst us of the belief in the superiority of hospitals maintained by the sympathy and humanity of the people as compared with those of foreign countries supported by the State. It may be difficult to say what are all the grounds for so strong a preference. But some of them are clear enough. It is believed that the voluntary principle implies a more personal interest in the institutions and a more humane treatment of the patients. Moreover, it cannot be doubted that on the score of economy the voluntary are to be preferred to the State- or rate-aided institutions. Another and perhaps the most fundamental ground for the preference is to be found in the view that hospitals are essentially charitable institutions for the use of poor persons, in exceptional straits from sickness or accident, needing help and appealing to the good Samaritan of all creeds.

It is not perhaps more than a coincidence that these strong expressions of preference for the voluntary hospitals coincide very much in point of time with a speech by the Duke of DEVONSHIRE on the occasion of the opening of two wards in the new wing of the West London Hospital in which his Grace seemed to associate the subject of the contemplated municipalisation of the vestries of London with that of a better hospital accommodation. We should be much concerned if we thought that the Duke of DEVONSHIRE intended to hint that it is the intention of the Government to include in their impending legislation any scheme for including the care of hospitals as one duty of the projected municipal bodies. Such an important proposal is not likely to reach us in any such casual way. But the friends of the voluntary system of hospital support cannot be too diligent in the use of such means as will increase this support and will deprive the advocates of a different system of any excuse for altering the existing one which is the glory of England and the admiration of foreigners. One means of doing this is in the careful restriction of hospital help to the class for whom it was originally intended and it is gratifying to us to notice that at Monday's meeting Mr. R. B. MARTIN, M.P., made pointed reference to the honest efforts of hospitals to ascertain the fitness of patients to receive attendance in accordance with the recent resolution of the Council making such efforts a merit in hospital administration.

IT would be difficult to imagine worse impeachments, professionally and morally, than those brought against Dr. DAVID WALLACE, a medical man practising at Beckenham, who was indicted at the recent Kent Assizes for having feloniously procured abortion on a young unmarried woman named WARRILOW. A second charge which was not proceeded with but for which Dr. WALLACE was committed by the magistrates was that of having by criminal assault been the author of the prosecutrix's condition, a condition which rendered the first-named crime possible.

The facts were as follows. In 1897 Miss WARRILOW suffered from retroflexion of the uterus. She consulted a medical man at Eastbourne who inserted a pessary. The treatment gave marked relief, but on discontinuing the use of the instrument the misplacement recurred, whereupon Dr. WALLACE, who was called in, re-inserted the support. As alleged by the prosecution Miss WARRILOW on March 11th of this year went unattended to the house of Dr. WALLACE to have the pessary removed. It was upon thi occasion that misconduct was stated to have taken place without the consent and without the knowledge of the patient. It was not suggested that force was used or that the passive agent was hypnotised; the theory put forward was that she fainted from the pain incidental to the removal of the pessary and whilst unconscious was ravished. In the face of Miss WARRILOW'S evidence that she remembered nothing unusual having happened, that she walked home after her visit to Dr. WALLACE, and that there was no circumstantial proof of molestation, we fail to see a *primâ facie* case

Digitized by Google

against the accused. Moreover, a person does not recover immediately and completely from an attack of syncope and nothing was elicited as to any "coming to"; indeed, it was mere surmise that there was any fainting at all. As the menstrual periods did not occur on three occasions Dr. WALLACE testified that he considered the case one of amenorrhœa consequent on retroflexion and to induce menstruation he introduced a sound into the uterus on May 26th and May 27th. On the second date free hæmorrhage occurred and to check this a mixture containing ergot was prescribed, but this was not taken. Shortly afterwards products of conception were expelled and it was this fact that led to a conversation between Mrs. WARRILOW, the girl's mother, and Dr. WALLACE. The former asserted that Dr. WALLACE, when interrogated as to his knowledge of the patient's recent condition, replied that "he was very sorry; he knew he was the cause of what had happened, and hoped he would be forgiven." This was clearly open to an innocent interpretation, but Mrs. WARRILOW averred that the following significant remark also fell from the accused: "I could not resist the temptation." If the jury could have unconditionally accepted Mrs. WARRILOW'S testimony as to this they would have been logically bound to convict Dr. WALLACE of more than one odious crime. But we quite agree with Mr. Justice HAWKINS who tried the case that counsel for the prosecution went too far when he said that the jury must come to the conclusion that perjury on one or other side had been committed. The late Mr. Justice STEPHEN once said in court that a jury should accept with hesitancy mere hearsay evidence of a conversation as probably no two persons would exactly reproduce from memory what had been said in the hearing of each. When Mrs. WARRILOW became acquainted with the fact that her daughter had been *enceinte* her mental condition must have been considerably perturbed and she may easily have assumed that Dr. WALLACE'S words "I am to blame for this" were a confession of guilt although the conclusion was utterly unwarranted by the premisses. With this belief it was easy to wander from the actual truth and to pick up words suggested by such belief and consistent with it but which may never have been spoken. This in our opinion is the explanation of Mrs. WARRILOW'S most significant piece of evidence which we should hesitate to classify as deliberate perjury.

That cessation of the periods, enlargement of the uterus, and general disturbance of the system might have led Dr. WALLACE to hold his hand was conceded by his counsel who rightly urged that a young practitioner ought not to be judged by the highest standard of attainment such as would be expected of an older physician or of one specially experienced in obstetric medicine. We would go further and say that in a question so argumentative a very considerable margin should be allowed to every medical man for errors of observation and judgment. We remember an instance in which a distinguished gynæcologist diagnosed a condition of pregnancy of three months' duration as a case of anteversion of the womb and unintentionally induced abortion by the very treatment adopted by Dr. WALLACE. From these considerations it was with feelings of relief and satisfaction that we learned the decision of the Maidstone jury to acquit Dr. WALLACE.

Annotations.

"Ne quid nimis."

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

WE have already written on the scheme for founding a medical graduates' college and we see no great reason to alter the opinions which we guardedly expressed in June.[1] It is impossible to deny that there is much that is interesting in the scheme. It is equally impossible to deny that there are aspects of it as elaborated in the circular before us to excite criticism and even anxiety. The objects of the scheme are shortly, firstly, to assist medical practitioners in their desire to keep themselves up to the best knowledge and practice of the day and, secondly, to make it easier for the sick poor to have their diseases considered in consultation with reference to diagnosis and treatment. The objects are good. The only question is whether they cannot be attained by the use of existing hospitals and societies and whether the new institution, either by its success or its failure, may not prove a source of disappointment and regret to the profession and even to those who promote it. If the objects can be accomplished with existing institutions it is clearly undesirable to create a new one. As we read the laws and constitution of the college it does not appear to us that it will differ very much in its objects from one of our existing medical societies and the proceedings at one of its meetings will very much resemble those of a clinical night at the Clinical Society or the Medical Society where cases are shown and a discussion on the nature and treatment of them takes place. Similarly we see no advantage to the sick poor in the way of consultation that is not either accessible to them now or that might not easily be arranged at any of our hospitals. A central office is proposed to be erected for giving information relating to educational opportunities, operating days at hospitals, and other information which is constantly supplied in the Students' Number of THE LANCET, and in our weekly issue and those of our contemporaries. We are not without fear that the provision for hospital accommodation and for consultations will involve a serious extension of the existing abuses of hospitals by other classes of society than those which now abuse them, to the injury alike of consultants and general practitioners. We recognise the precautions that are to be taken in theory to prevent such abuses, but in practice and in an institution like that which is pictured in the circular such evils will be apt to assert themselves. Finally, the undertaking seems bold in a financial respect. A very considerable income would be necessary to support such an establishment and to pay the officers who are to carry on the work. We should rejoice in any improvement in the methods at present in vogue at hospitals and societies for making them more useful to medical practitioners, but we scarcely see the justification of a brand new college and polyclinic the success of which would imply new risks of hospital abuse and the abstraction of much energy and support from existing institutions.

VOLUNTARY HOSPITALS.

CHRISTMAS is very near us and the usual flood of appeals for money pours in. No form of charity is more worthy of support than that which provides medical aid for the sick poor. There may be differences of operation but the wolf of poverty stands at the door of nearly every metropolitan

[1] THE LANCET, June 4th, 1898, p. 1545.

Digitized by Google

hospital; they do what they can and yet there is an enormous mass of poverty and sickness still unrelieved. Despite the efforts of the religious bodies and of the thousands of brave men and women who go out to help the poor, despite the millions spent by the Poor-law bodies, the School Board, and the London County Council, ignorance, crime, poverty, and sickness still abound. And though but little impression seems to be made by all these agencies we must think of what the state of matters would be if for one year the fountain of relief, both voluntary and involuntary, were dried up. But as concerning the hospitals it is noteworthy that the London hospitals are badly off mainly because they are in London. True, they are at the fountain head of wealth and knowledge, but it must also be remembered that the agglomeration of cities called London draws to itself the poor, the sick, and the failures from all parts of the United Kingdom. The metropolitan hospitals are not merely metropolitan, they are national, and the time seems to be approaching when they will have to be assisted not only by dwellers in the metropolis but by provincial aid as well. An appeal now before us says: "The hospital is close to the termini of three railways serving the northern suburbs and is consequently most conveniently situated for patients arriving in London by these lines, and from all parts of the country poor patients are sent by their medical advisers for special treatment by our staff." Now here we have one great reason why the hospitals of London are always in debt. They serve not only their own immediate neighbourhood but practically the whole country. In some cases of course this is necessary, but anyone who has ever worked in a big hospital must have seen hundreds of patients who came for relief because in the first instance they had something the matter with them, and also because their complaint afforded an excuse for a trip to London. We can quite sympathise with the needs of many a hospital, but the present state of chronic impecuniosity cannot go on. Either the London hospitals must find some means of confining their ministrations to London people or else the provinces, if the provinces use the charitable institutions of the metropolis, must assist in supporting them.

NAVAL PHARMACIES.

THE problem of the storage of drugs and medical appliances on board men-of-war is one of considerable magnitude and importance, not only from the point of view of the officers and sick-bay attendants whose efficiency and reputations are to a great extent concerned, but also from that of their gallant patients who are clearly entitled to the best possible treatment while suffering from sickness or wounds during their term of service afloat. It has been recently asserted that even with regard to elementary matters the medical equipment of the British Navy leaves much to be desired and possibly in some few of Her Majesty's ships there may be grounds for the charge, but we cannot for a moment believe that in a department so intelligently administered as our Naval Medical Service the remediable blots and lacunæ can be either numerous or extensive. Hitherto in the French Navy it has been the custom to keep the whole of the medical stores in cupboards no two of which are alike as to size or shape, the receptacle in each case having been constructed according to the exigencies of a space grudgingly allotted and all too narrow for the requirements. In order to remedy the confusion, waste, and inefficiency thus inevitably arising, Dr. Rouvier, principal medical officer at Cherbourg, has devised a series of portable *coffres*, or chests, and Ministerial approval having been accorded to them these appliances are to be taken into general use throughout the fleet on and after the 1st of January next. In the *Archives de Médecine Navale* for November Dr. Rouvier gives a brief description of his coffers which are five in number, two for medicine marked respectively *Ma* and *Mb*, two for dressings marked *Pa* and *Pb*, and one for use during an action marked *Fa*. The coffers *Ma* and *Pa* contain all that is necessary for treating 100 men during six months—all, that is, except a few cumbrous articles as well as some bulky non-perishable material for which accommodation has to be provided elsewhere. Each *a* coffer is divided by a horizontal diaphragm. The lower division contains only substances in constant use; the upper division contains a certain number of imperishable articles and also substances less constantly in use, such as silk, catgut, atropine, emetine, refills for ambulance satchels, &c. Coffers *Mb* and *Pb* are simply duplicates of the lower divisions in *Ma* and *Pa*, being intended as a reserve for re-stocking purposes. In addition to their horizontal diaphragms all the coffers are likewise subdivided vertically in order to facilitate access to the contents. When two or more coffers of the same kind are on board a vessel they can be superimposed in such a way that the contents of each face of a combined pair are equal to those of an entire coffer. When only a single coffer is available it can be made to revolve by means of an ingenious mechanical device. The greatest care has naturally been devoted to the stocking of the various coffers, but, as Dr. Rouvier points out, nothing on earth or ocean is stable and sooner or later modifications of the existing arrangements will be introduced. In order so far as possible to provide for this inevitable contingency the internal fittings have been reduced to a minimum and where it was practicable have been made moveable. The partitions between the several phials, pots, &c. (each of which shows the date of its filling), consist of galvanised iron wire so as to provide for a certain amount of elasticity and here and there a few compartments have been left empty for individual preferences. In conclusion Dr. Rouvier informs his readers that he has drawn up a memorandum to accompany his coffers, embracing a system of account keeping, directions for re-stocking, and sundry other matters; but that as ministerial sanction has not yet been notified and his proposals may consequently be altered or even rejected altogether he deems it best to withhold the document for the present.

PROGRESSIVE BONY ANKYLOSIS: "ARTHRITIS OSSIFICANS."

A CONDITION which though not very uncommon in man and the lower animals has not received much attention is bony ankylosis of the vertebræ converting the column in extreme cases into one solid piece—spondylitis deformans. In horses it is not uncommon and is a predisposing cause of fracture. Specimens exist in most museums. Often accompanying this spinal disease is ankylosis of other joints, sometimes of almost all in the body. In an annotation in THE LANCET of Nov. 5th we called attention to a form described by Dr. Pierre Marie and termed by him "spondylose rhizomélique" because the ankylosis affects the spine and the roots of the limbs. That distinguished clinician appears to regard it as a special disease ("une entité clinique très spéciale"); but we fail to see how it can be regarded as anything more than a form, and perhaps only a temporary form, of this previously recognised general ankylosis. No doubt, his clinical acumen has seized one of the types of the disease and very possibly the shoulder and hip-joints are more prone to be attacked or are attacked earlier than other joints. But even according to his description the term "rhizomélique" is not comprehensive, for he mentions limitation of flexion of the knees as a feature of the disease, and swelling of the sterno-clavicular joint as present in one case. The *Journal of Pathology and Bacteriology* (December 1896, and March and June, 1897) contains valuable papers by

Digitized by Google

Dr. Joseph Griffiths on bony ankylosis in general and on this form, which he terms "universal bony ankylosis or arthritis ossificans," in particular. He gives an analytical table of 20 published cases; in none were all the joints affected; in about half nearly all were. The term "universal" cannot therefore be justified: "general" or "progressive" bony ankylosis would be more accurate. The joints become obliterated and the articular ends of the bones grow together. The disease usually begins in early adult life. The age of onset was from twenty-two months to thirty-four years, in the majority between twenty and thirty years. It is more common in males than in females—14 cases to 4. This should be compared with Dr. Marie's statement of his 7 cases: "All occurred in adult males." The progress of the disease is slow—subacute or chronic; it takes months and even years to involve and fix the greater number of joints in the body. The joints are attacked in succession. In the subacute form there are swelling, fixation, and pain in the joint which subside after weeks or months, leaving the joint fixed but not deformed. In the chronic form there is no swelling, but pain and stiffness occur leading to fixation. There are cases in which almost the whole skeleton is thus joined into one rigid piece of bone; in others the spinal column is the chief, if not the only, seat of disease; in others the limbs alone are involved. From the examination of museum specimens Dr. Griffiths concludes that ossifying arthritis probably commences by the formation of spiculated growths at the articular margins of the bones which bridge over the joint cavity and fuse. These marginal growths differ from the "lippings" of rheumatoid arthritis; they arise independently of the articular surface and are not covered by articular cartilage, whereas the latter are, as it were, a direct extension of the articular end of the bone. Indeed, in ossifying arthritis the marginal growth takes place into the surrounding connective tissue—ligaments especially—and the joints are obliterated centripetally. When fusion has occurred the external ridges of bone tend to disappear, leaving the external surfaces of the bones smooth and even. In this description Dr. Griffiths does not apparently refer to the changes found in the spine; here buttresses of bone are formed connecting the vertebræ and remain permanent. The anterior common ligament may be replaced by a splint of bone. As to etiology, the following exciting causes have been noticed: (1) exposure to cold, wet, and fatigue; (2) worry; (3) gonorrhœa; and (4) injury. In one instance the disease was of congenital origin. The pathology is obscure. Whilst showing differences from rheumatoid arthritis the view that it is allied to, or a form of, that disease has some evidence in its favour. On the other hand, an alliance with an equally obscure disease—myositis ossificans—seems to be feasible. Both diseases consist in abnormal ossification of mesoblastic tissues and both may be of congenital origin. As bone normally develops from connective tissue, may not these changes be regarded as a physiological process becoming pathological by extension?

A HISTORICAL DRAMA BY AN EDINBURGH PHYSICIAN.

THE addition of another name to the list of eminent medical men who have ventured into the highways of general literature is always an event worthy of note and one which cannot fail to arouse much interest in medical circles. It will not only interest *alumni* of Edinburgh to know that a former teacher who is still a Professor is shortly to appear in this *rôle*, but it will interest the profession at large wherever Sir Thomas Grainger Stewart's name is known. The secret has been well kept, for it only begins to be known now when some of the advance copies of his book have been seen. The work in some aspects is ambitious, for it takes the form of a Chronicle Play in blank verse. The theme is a historical one of the time of Mary Stuart and the leading personage is the Regent Moray. Sir Thomas Stewart has entitled his work *The Good Regent* which in itself sufficiently indicates the estimate he has formed of his hero. In the preparatory note he says that he threw the story into its present form by way of recreation during an autumn holiday and he craves indulgence for the "apparently ambitious form in which it appears." We do not for a moment suppose that Sir Thomas Stewart has any ambition to be regarded as a poet but we wish all poets wrote as readable verse as his is, judging from a rather rapid survey of the pages of his work. That Sir Thomas Stewart should have chosen a historical theme and found it in one of the most important and momentous times in the history of Scotland is only what might be expected from a man with the historical tastes and literary faculty which he is known to possess. We meanwhile only give this preliminary notice of a work which will not fail to attract attention on account of its historical representations, on its writer's account, and on account of the form in which it appears. We welcome it, for it is always pleasant to know what a man is beyond what he is as a physician, and the writer of this drama does not fail to show the direction in which he leans and the considerations which appeal to him.

INFANTILE SCURVY AND ARTIFICIAL FOODS.

A DISCUSSION on Infantile Scurvy took place at a recent meeting of the Société Médicale des Hôpitaux, Paris, and is recorded in the *Journal de Clinique et de Thérapeutique Infantiles* of Nov. 17th and 24th. According to M. Netter, who showed a typical case of this disease, its causation has to do not merely with the use of artificial infant foods which has of late years become so general but even with certain modern methods of sterilising ordinary cow's milk. In his own case the child had been brought up on milk which was "maternised," that is, sterilised by heat and deprived of a part of its caseine. He suggests that milk is impoverished by this process and consequently loses its anti-scorbutic properties. M. Comby also showed an example of the disease in a child three months old, and here also the diet had been "maternised" milk. In the absence of any other probable cause in the form of dietetic errors and in view of a very marked improvement followed by a rapid recovery when fresh milk was adopted as the staple food the appearance of scurvy was not unnaturally attributed by both of these observers to the changes produced in the milk by "maternisation." They likewise drew attention to the fact that infantile scurvy though rare in France is much more frequently met with in Great Britain and in the United States of America. The cause assigned for this international disparity is doubtless the true one—namely, that in default of the maternal breast French custom prefers a wet-nurse, while in this country and in America recourse is commonly had to some one of a multitude of infant "foods." M. Variot who also spoke on this subject, while admitting the connexion between infantile scurvy and an artificial diet, stated that he had not found that this connexion existed where the child's nourishment consisted simply of sterilised cow's milk. At the Bellville Dispensary 500 infants were thus fed while under his care and no case of scurvy occurred among them. On the other hand, he had found milk thus prepared to be invaluable as a nutrient in infantile atrophy. Notwithstanding some difference of opinion which is evidently the effect of mutual misunderstanding and more apparent than real, we may therefore conside the views of these various observers as agreed on the essential point in this discussion. For each the occurrence of scurv

Digitized by Google

in the infant has only one explanation—a faulty, because too artificial, diet. There is indeed no other possible theory of its causation and this is a fact which the practitioner must always bear in mind. At the present time the market is inundated with every conceivable form of milk and milk food, peptonised and non-peptonised, and with meat extracts in addition, all professedly most suitable for the nutrition of infants. There is unquestionably a serious danger that among so many elaborated feeding contrivances a child may miss that simpler chemical product of nature's laboratory for the digestion of which the alimentary canal was particularly intended. It is also noteworthy that in cases where the choice of milk is left to the direction of a medical adviser, where sterilisation is practised in its simplest form, and peptonisation if needed, as it sometimes may be, is carried out under medical direction, scurvy-rickets, atrophy, and most of the other digestive troubles of infancy are conspicuously absent. It should always be remembered that over-refinement in the diet of infants is an error which usually defeats its intended purpose and results in their starvation.

DEATH UNDER CHLOROFORM.

A PATIENT died from the effects of chloroform at the Salisbury Infirmary on Nov. 14th. We are indebted to Dr. F. F. Lee for kindly sending us corrected notes of the fatality. The patient, an alcoholic subject, aged sixty years, was admitted into the infirmary seeking relief for fixation of the hip and other joints the result of chronic rheumatism. He was placed under chloroform and the joints were forcibly moved. He struggled, but no further trouble appears to have arisen on this occasion. He desired after this to have other modes of treatment tried but eventually allowed himself to be again given chloroform with a view to further forcible movements being used. This was four months after admission. On the second occasion of the administration of chloroform the junior house surgeon gave the anæsthetic, but by what method is not mentioned. The patient struggled very violently and eventually passed under the influence of the anæsthetic. The forcible movements were then easily performed. The administrator at the end of the manipulation called attention to the man's condition which was so bad that he appeared as if dead. No doubt this was so as no means adopted to effect resuscitation produced any result. The amount of chloroform given is reported as being 1½ drachms. The post-mortem appearances showed opacity and thickening of the dura mater with adhesion to the skull. The organs were healthy save for adhesion of the capsules to the kidneys. There had been no albuminuria during life. Although the death is attributed to sudden failure of the heart the phenomena recorded seem far more consonant with that form of sudden death in which both the circulation and the respiration fail simultaneously and with extreme rapidity—a mode of death which results from the patient receiving a lethal dose through taking in a too concentrated vapour during struggling. The struggles of a patient commonly arise from "pushing" the anæsthetic—a common mistake even among experienced chloroformists and the bane of less proficient anæsthetists. It is a common error to suppose that a drachm or even less cannot produce chloroform poisoning. It is simply a question as to how dilute the vapour is. Even a few minims volatilised suddenly and inspired in a few deep gasps such as accompany struggling are quite able to be rapidly conveyed to the vital centres and to cause paralysis of the medullary centres and death. Even at the risk of much loss of time it is best to give a low percentage of chloroform vapour and adhere to it. The ease with which the rigid joints were moved was probably the result of the extreme muscular flaccidity following the profound narcosis.

THE CASE OF THE LATE MR. HERBERT KINGSLEY HUNTER.

WE understand that the appeal in this case will be heard at 10.30 A.M on Saturday next in the Lord Chief Justice's Court. The case has excited much interest in the profession on several grounds apart from the point of law to be determined by this appeal—viz., the right of a licentiate of a society of apothecaries to use the title of "Physician and Surgeon." Our readers are aware that the appellant has unfortunately recently died—an event which, in the absence of legal knowledge, we should have expected to end the appeal. But this does not appear to be the case.

A HERO'S DEATH.

INFORMATION has been received of the death of a ship's medical officer owing to a very noble act. The medical officer in question, whose name was Murphy, was serving in a steamer plying between Canton and Hong-Kong. On the voyage a Chinese child fell out of his mother's arms into the sea which was running very heavily at the time. Dr. Murphy immediately plunged in after the child, but the sea was so heavy that it was two hours before he was picked up and he never recovered from his exertions. His death was deeply deplored by all on board. We are far from thinking that there were not many others on board the steamer who would have been perfectly ready to do the same noble act, but Dr. Murphy was the one to whom the opportunity came and we are proud to think he was a member of the medical profession. From accounts to hand we do not know whether the child was saved or not.

THE PENNSYLVANIA SOCIETY FOR THE PREVENTION OF TUBERCULOSIS.

WE have received the report of the above society for the year ending April 13th, 1898. The society has worked quietly with but one end in view—namely, the education of the community in a knowledge of the true nature of phthisis and of the means now considered necessary to control or conquer this disease. The means by which this end is sought to be obtained are: (1) by the publication and distribution of pamphlets; (2) by constant endeavour to induce those in influential positions to use their earnest efforts to prevent the spread of the disease; and (3) by striving to obtain the requisite conditions whereby those early afflicted may be restored to usefulness, or for those far advanced the safeguarding which will prevent the communication of infection to others. We cordially applaud these objects and would draw attention more especially to the last-named clause—namely, the safeguarding of those phthisical patients far advanced in the disease in order to prevent them becoming dangerous to their fellow-creatures. The problem is a most difficult one. The sputum in such cases is often almost a pure culture of tubercle bacilli. Patients of the poorer classes are in a most deplorable condition; they must either remain at home in ill-ventilated abodes, perhaps with many people living and sleeping in the same room, or go to the workhouse infirmary, which they often refuse to do, although these institutions are most excellently managed and in them every attention is given to the comforts of the patients. Owing to want of space the general hospitals are adverse to admitting them and the special hospitals for diseases of the chest refuse "advanced cases," for they consider that more good can be done by attending to the early cases. The workhouse infirmaries, then, are their only resource. The "homes for the

Digitized by Google

dying" are so few that necessarily but few phthisical patients can gain admission. It is therefore of the utmost importance that the friends of the patients should be made acquainted with the infectious nature of the disease and it behoves every medical man attending such cases to see that due precautionary measures against the spread of the malady are taken, the most important of which are the reception and disposal of the sputa and the treatment of linen which may become soiled by them. These are too well known to our readers to need further explanation.

ATAXY OF THE RIGHT ARM.

DR. OLMSTED gives an account in a recent number of the American *Journal of Nervous and Mental Diseases* of the case of a man, twenty-seven years of age, who suddenly developed diplopia associated later with slight failure of vision. There was apparently weakness of the right external rectus but no change in the fundi. About three months after the onset of diplopia he experienced numbness in the thumb and in the index and middle fingers of the right hand, and a pricking sensation in the right lip and side of the face. There was difficulty in writing. There was nothing significant in his family or personal history. He was a well-developed man with normal gait and appearance and with no evidence of disease of abdominal or thoracic viscera. There was slight lateral nystagmus on deviation; the pupils were equal and reacted normally. The right arm became, several months after he was first seen, distinctly ataxic and there was much impairment of muscular sense and later also of sensation to pain, although tactile sensibility remained unimpaired. The left knee-jerk was active, the right very sluggish, and it was also noticed that on rising suddenly from a sitting to a standing posture there was a tendency to go forward and a little to the right. The fields of vision were markedly contracted for both white and red, the contraction being greater in each temporal field. The fundi appeared to be normal. Dr. Olmsted does not venture on a diagnosis but promises to watch the case and report its future progress.

DIPHTHERIA AT GREAT YARMOUTH.

AN action was heard on Dec. 7th and 8th in the Queen's Bench Division, before Mr. Justice Lawrence and a common jury, in which a tailor named Alexander sued a town councillor and a member of the Sanitary Committee of Great Yarmouth, by name Foulsham, for breach of contract in neglecting to supply a sanitary water-closet to a house which plaintiff rented from defendant. It was alleged that in consequence of this neglect two of the plaintiff's children contracted diphtheria and died. In March, 1894, the plaintiff and defendant entered into a verbal agreement whereby the plaintiff agreed to take the house in question and the defendant agreed to provide a water-closet and to fix it properly. The plaintiff entered into possession of the house and the closet was fixed, but according to the plaintiff the work was improperly done. All the Alexander children were attacked by sore throat and two of them died from diphtheria. The defendant denied the allegations and said that if the drains were defective they were rendered so by the carelessness of the plaintiff. The two children who died had attended the Wesleyan school. The plaintiff said that the drain had been constantly flushed with water. Dr. Dudfield expressed the opinion from what he had heard in evidence that the children had caught diphtheria from bad drains. Mr. Hassall, the sanitary inspector, said that until diphtheria broke out no complaint had been made as to the state of the plaintiff's premises. When he examined the place the drain was blocked owing to want of flushing and the house and yard were very dirty. The fall was quite enough. Dr. Bately, the medical officer of health of Great Yarmouth, and Sir Hugh Beevor, M.D. Lond., gave it as their opinion that the two children had contracted diphtheria from school infection. A bricklayer said that he had found the drain upon one occasion stopped with a house-flannel. The jury found for the plaintiff, damages £250. Counsel for defendant asked for a stay of execution on the ground that the amount of damage proved could not amount in the circumstances to the sum awarded by the jury. A stay was accordingly granted.

A MEDICAL ALDERMAN OF THE CITY OF LONDON.

ON Dec. 8th the ratepayers of the Langbourn Ward met to elect a new alderman in the place of Sir Joseph Savory who has succeeded to the position of Alderman of Bridge Without vacant by the death of Sir Stuart Knill. Sir John Lubbock nominated Dr. Thomas Boor Crosby who had been a member of the Court of Common Council for twenty-one years. Mr. Fortescue Flannery, M.P., seconded the nomination, and there being no further nominations Dr. Crosby was declared duly elected, the election being unanimous. On Dr. Crosby rising to accept the position he was received with hearty applause. It is with the greatest pleasure that we join our congratulations to those of Dr. Crosby's brother citizens, for it is no small pleasure to us to be able to chronicle the election of a member of our own profession to the ancient and honourable office of an alderman of the City of London. Thomas Boor Crosby received his medical education at St. Thomas's Hospital and qualified as L.S.A. and M.R.C.S. Eng. in 1852. In 1860 he became F.R.C.S. Eng. by examination and in 1862 graduated as M.D. at the University of St. Andrews. He has been President of the Hunterian Society and chose for his presidential oration in 1871 the subject of "Modern Medicine." He is a Lieutenant for the County of London and is in practice, together with his son, at Fenchurch-street. We have lately seen a medical man Chairman of the County Council and we now look forward to the possibility of a member of the same noble profession reaching an even higher post—namely, that of Lord Mayor of London.

MEDICAL RELIEF.

THE last of the course of eight lectures given at the Portman Rooms by various well-known medical men and others interested in charitable work was delivered by Dr. J. B. Hurry on Dec. 9th, the subject being "The Self-supporting Dispensary and District Nursing Association." Dr. Hurry argued that the average working man cannot afford to pay for the expenses of a long illness out of his ordinary wages. Hospitals and Poor-law relief do not entirely meet the want and besides they tend to pauperise those who should possess self-reliance and the wish to do all for themselves that they can. Medical attendance has, it is well known, been for years organised on a provident basis and in Dr. Hurry's opinion the time has now come for nursing to be provided on the same system. Dr. Hurry's model scheme is shortly as follows. The benefits of the institution can be enjoyed under three conditions. Firstly, those members who were desirous of laying by something against a rainy day could pay in small sums, weekly, we suppose, as an insurance premium in the same way in which ordinary friendly societies are managed. Secondly, persons who have not insured beforehand can become members by paying an entrance fee which should be high enough to make the applicant consider whether it would not be wise in future to become an insuring member by paying in beforehand. Thirdly, cases of emergency can obtain benefit by obtaining a subscriber's letter which should represent a sum equal to

Digitized by Google

the fee paid by the second class. Dr. Hurry considers that a sum of from 2*d.* to 3*d.* per week would suffice to keep the institution when once fairly started in a satisfactory condition. We think there is a good deal to be said for Dr. Hurry's scheme with the exception of the clause concerning subscribers' tickets, but we are glad to see that he himself says that this should be omitted if possible. One district nurse in a town at any rate is considered able to look after the nursing required for some 4000 persons. The idea, as we have said, is a good one, and if only pains are taken to prevent abuses creeping in it is one well worth a trial. Of course, all profits after payment of necessary expenses must be divided *pro ratâ* between the medical officers and the nurses, and also there should be some arrangement whereby any medical practitioner in the town or district could be on the staff of the institution if he so wished. With these safeguards we think the organisation of such a scheme would be of great value.

LUIGI GALVANI, the great anatomist of the Bolognese school and better known for his discovery of animal electricity, received on Sunday, Dec. 4th, at Bologna the honour of a centenary celebration—that of his death which took place on Dec. 4th, 1798. The occasion evoked the presence of the leaders of the local medical school and its orator was Signor Erminio Vitta, representing the committee of Italian telegraphists now organising a similar commemoration of Alessandro Volta. The proceedings were highly successful.

AT a meeting of the Childhood Society held at the Parke Museum, Margaret-street, on Dec. 8th Dr. Henry Rayner delivered a lecture on the Early Recognition and Treatment of Mental Condition, in the course of which he dwelt on the many signs of mental disorder in children and advocated the establishment of centres where young imbecile children could be received for a short time under efficient nurses who would be able to demonstrate to their parents how much good might be done by proper care.

A PRIVATE meeting of the National Association for the Prevention of Consumption and other Forms of Tuberculosis will be held at Marlborough House on Dec. 20th, under the presidency of His Royal Highness the Prince of Wales, to further the objects of this association. Lord Salisbury and Lord Rosebery are expected to be present.

THE case of Thomas George Senior, one of the "Peculiar People" who was found guilty in November last of manslaughter, came before the Lord Chief Justice and other learned judges in the Court for the Consideration of Crown Cases Reserved on Saturday last when the conviction was affirmed.

LIEUTENANT WARK, who was convicted last Saturday in Liverpool of procuring a criminal abortion, was sentenced to death, but as all our readers know, has since been reprieved. We defer comments upon the case until we know what sentence the convict is to receive.

MR. VICTOR HORSLEY will address the Manchester Medico-Ethical Association on the business done at the recent meetings of the General Medical Council this afternoon (Friday, Dec. 16th) at 4 P.M. in the Memorial Hall, Albert-square.

PRINCESS LOUISE on Dec. 7th opened two new wards in a wing which at a cost of £18,000 has been added to the West London Hospital.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

II.

WITH regard to the scope of our articles upon this subject we wish it to be understood that it does not include questions of what are known as Malthusian doctrines and the limitation of families, and that we do not touch upon these except to point out that the strong temptation to avoid maternity, if possible, does not only affect unmarried women who have to face the shame attaching to unchastity, and is not confined among married women to those who merely regard the bearing of children as irksome and painful and possibly expensive. There are large numbers of married people among the "domestic" class, a class not likely to reason or hesitate in such matters, who hold situations dependent upon their having no families, or "no encumbrances," as their employers term it in advertising for them. It would be out of place here to protest at length against this practice. We allude to it in order to emphasise the point that the incentive to purchase what seems an easy way out of hopeless trouble is very strong with a class not well able to resist it and we repeat what we have already said, that in our opinion quack medicines sold as curing "obstructions, irregularities, and suppressions" and advocated upon the same page as rubber preventives, check pessaries, vaginal injections, and the like must be bought frequently by women who believe that they are buying abortifacients and nothing else.

The men referred to in our first article on this topic as charged with blackmailing women and other offences are at the time of writing awaiting their trial at the Old Bailey; we cannot, therefore, comment on their case except to say that the evidence already given at the police-court serves to illustrate many of the evils which result from a traffic that has long gone on. That these evils must result seemed so probable to us that we undertook this inquiry in order that there might if possible be no question in the matter, while the arrest of these particular persons has rather delayed the publication of our articles than otherwise. In case we may be thought to labour our points and in case it may be suggested that neither the advertisements nor the trade will now continue, we must point out, firstly, that both advertisements and trade have flourished for many years, although most people would have thought that their character was obvious and that the meaning of an invitation sufficiently plain to attract the attention of ignorant young women would equally have arrested that of newspaper proprietors and of the police. Secondly, since the trial of the case of Owen *v.* Greenberg, to which we shall refer later, no important diminution in the number of these advertisements has been noticeable in spite of the attention then called to their character.

We now proceed to give the analysis of certain of the pills and potions which we have purchased in response, primarily or secondarily, to advertisements appearing in the public press. At the same time where they seem germane to this inquiry we print extracts of the correspondence which has taken place with the advertisers. For purposes of convenience in summing up our results and comments we place different letters of the alphabet at the head of each case as we consider it.

A.

The following advertisement has been given already in full last week:—

Ottey's Strong Female Pills quickly and certainly remove all OBSTRUCTIONS arising from any cause whatever, where Steel and Penny Royal fails. Invaluable for married women. By post, under cover, for 14 and 33 stamps, from THOMAS OTTEY, Chemist, 32, Hagley Road, Birmingham.

We have good reason to believe that this particular advertisement has been very widely distributed. Our first letter to the advertiser simply enclosed 1*s.* 2*d.* in payment and asked for a box of strong female pills as advertised, requesting that they might be so packed as to be safe from observation, the purchaser being represented as a servant and unmarried. In reply to this we received the box

Digitized by Google

of pills the analysis of which we give below. It was accompanied by two or three printed sheets extolling various specifics of an innocent character as well as the "female pills." A separate sheet is entitled a "check circular" and recommends taking the pills before and after sexual intercourse with a view to preventing conception, while another leaflet deals with them in considerable detail, giving directions for their general use as emmenagogues and for other purposes as well. These directions precede a paragraph, headed in large capitals "For married women," in which the dosage and diet for these patients are more or less elaborately laid down. Then follows the following sentence heavily underlined, "After success the pills should be taken regularly, exactly same as check circular," and attention is called to "Extra Strong pills" for very obstinate cases at 5*s*. 3*d*. and to "The Strongest" at 10*s*. Further quotation or comment, however, on the objects for which the pills are sold is rendered unnecessary by a slip of paper which was wrapped round the box. On this we find in manuscript the following recommendation:—

If these don't do all you wish send for the Extra Strong Pills at 5*s*. 3*d*., or The Strongest at 10*s*. per box, and say how far over. If these don't do it the Strongest will shift anything.

Wishing to test this advertiser's "Strongest" pills and in order that there might be no question in his mind as to the purpose for which they were required, a second letter was written enclosing 10*s*. and stating that the sender believed herself to be four months advanced in pregnancy. If anyone should find in our conduct here matter for unfavourable comment on the ground that we have tempted Mr. Thomas Ottey to sin we have to say that we found in him so willing an accomplice that we can hardly have been his seducers and, secondly, that it is useless to fight a certain sort of stink with rose-water. The pills sent in reply to our second letter were accompanied by similar printed matter to that sent with the first instalment of pills, by printed directions for taking this "Extra Strong" and "Strongest" pills and by another slip of written matter in the same handwriting as the first. We quote without comment a passage from the printed sheet and the whole of the written slip:—

Print: "..... continuing the treatment until the usual signs of success (slime, jelly stuff, streaks of blood either *front* or *with the motions back way*, with strong forcing pains, backache, pains in the limbs, etc.) have been present six or eight days running, when a foot-bath and a dose of Composition Tea or Holland's Gin may sometimes be found useful, though they are not necessary. When the Pills have effected the desired relief, the periods usually commence again, from five to eight weeks afterwards, sometimes earlier. The Pills are certain if taken long enough, and after success should be used regularly by all patients *exactly* same as Check Circular to prevent future trouble, prevention being much better than cure.

Written: "You are at a most difficult time, still the pills will do it if the internal organs are right.

"We don't expect it as courses so try to get heavy forcing also streaks, clots, strings, bits of skin-flesh, all back way 14 days running, then you will be safe."

The following is an analysis of the pills:—

(*a*) Pills sent in response to our first communication and presumably

OTTEY'S STRONG FEMALE PILLS.

Moisture, 17·24 per cent.
Mineral matter, 24·73 per cent., consisting chiefly of iron.
Organic substances, 58·03 per cent.

An aqueous extract of these pills was exceedingly bitter to the taste and of a light yellow colour. From this extract chloroform dissolved out an intensely bitter principle which yielded in a very satisfactory way colour reactions which were absolutely identical with a pure colocynth residue.

There was no evidence of aloes or of any volatile oil.

The directions sent with these pills were as follows:—

For married women. Take three or four Pills for a dose three times a day, using a foot-bath and taking a dose of Composition Tea once or twice a week.

(*b*) Pills sent in response to our second communication and presumably

OTTEY'S "THE STRONGEST" PILLS.

Moisture, 16·60 per cent.
Mineral matter, chiefly iron, 22·16 per cent.
Organic matter, 61·24 per cent.

These pills are substantially the same as (*a*) with the very important difference that they were found to contain savin oil. The quantity of savin oil amounted to not less and probably more than 34 minims per 100 pills. Thus 12 pills contain slightly more than the maximum dose of this irritant oil as laid down in the 1885 Pharmacopœia.

The directions for taking these pills and also the Extra Strong Pills were as follows:—

Commence after breakfast or that part of the day which is found most convenient and least likely to cause purging in the night and take four pills three or four times a day between meals (some can take the doses best between tea time and very late at night), gradually increasing the dose until twenty-four pills are taken daily.

* * * * * * *

Patients who are not able to undergo the proper full treatment should take only twelve or what number they can bear (very many even win by only taking from four to six of the best pills every night at bed-time) of the strongest pills daily until successful, taking three or four pills for a dose every three or four hours.

We conclude our present notice of Mr. Thomas Ottey's wares by quoting from Squire's Companion to the British Pharmacopœia (sixteenth edition) certain references to savin, a scheduled poison which may only be sold under the well-known conditions that the vendor be a pharmaceutical chemist or a medical man and that the purchaser sign a book with his name. Under the head of "medicinal properties" we find there, "A powerful local and general irritant ..... a powerful emmenagogue." Under the head of "Savin Oil" we find the dose set down as one to four minims. In the therapeutical classification of remedies at the end of this well-known book of reference we find "savin" described as one of the substances "which promote the contraction of the uterus and facilitate the expulsion of the contents." Savin is not included in the British Pharmacopœia any longer, but in the edition published in 1885 the maximum dose of the oil is given as four minims.

B.

The advertisement in this case was as follows:—

Married and Single Ladies should send at once for FREE ADVICE and information of Priceless Value. Address in confidence:—PROFESSOR LESLIE, 34, George-street, Chester.

Our first letter simply invited the "free advice and priceless information."

In reply we received sundry printed documents and a letter which we reproduce in full:—

34, George-street,
Chester.

DEAR MADAM,—Yours to Hand in reply I Enclose you my Price Lists etc. should you Require my Remedies I should strongly advice you to try my 10*s*. 6*d*. Mixture although the 4*s*. 6*d*. Packages is very good in slight causes Will you kindly favour me with a few Particulars I should then be Better able to advice you Which Whould be Held in strict Confidence. Awaiting your Reply

Yours Respectfully
J. LESLIE.

To this person we wrote again, enclosing 10*s*. 6*d*. and asking for a bottle of remedy, the writer being represented as probably about three months gone with child. Instead of the bottle ordered we received in reply the following letter which again needs no comment from us:—

George-street,
Chester.

DEAR MADAM,—Yours to Hand with 10*s*. 6*d*. Enclosed I am sorry things are so far gorn I am afraid this wont do it But why not try a Larger Case You know things are far gorn But still not to Late I should recomend you a Larger Cace it Whould Be More Certain that is I could send you four Large Bottles for 30/1/6 thirty-one Shillings and Six Pence it Whould be certain and Cheaper as by Having the four you Whould Be saving the 10/6 Now Just consider this Over as you cannot Let things go much further it Whould be to Late if you Deside to Place your Case in my Hands send the Postal for £1 1*s*. 6*d*. one pound one and sixpence I will then send You four Large Bottles that whould Be More Certain to act Of course if you only wish the 10*s*. 6*d*. Bottle I can send it On at Once But I should strongly recomend the Larger Case Will you at the Same time Kindly imform me when Writing if you are married or single and what age are you etc. so that I can Better understand your Case

I may mention that all Letters sent to me are strictly confedental

Awaiting your Reply
Yours faithfully
J. LESLIE.

P.S. Do you think you could Pay me a visit if so kindly say as I take an interest in all my clients and will endover to Do my Best for you My 10*s*. 6*d*. bottle is very strong But I am afraid the one wont Be enough But four will be certain in any case.

Our reply to this was to the effect that the person requiring the "remedy" was thirty years of age and married. The sum of £1 11*s*. 6*d*. was enclosed and we note that the fact that we inadvertently sent 10*s*. too much is not remarked upon in "Professor" Leslie's reply. Three bottles duly arrived at intervals of a day or two, the first bottle being preceded by another letter, which we reproduce:—

George-street,
Chester.

Dear Madam,—Yours to Hand With Postal Order Enclosed, By Return I am forwarding you a Package of My remedies I Have Made

Digitized by Google

the two Bottles into One the remainder of the remedy I shall send you On Tuesday, I am sending them this way so that it will arrive safe to you through the Post and not Look to Bulky as I think it will Be Best Kindly Let me Know when you are well again

Yours Faithfully
J. LESLIE.

P.S. Parcel Tuesday with further Directions.

The last bottle of the "case" was accompanied by a further communication which we reproduce:—

Chester.

DEAR MADAM,—I am sending you the Last of the Case You Should Be Well again By the time you finish this Bottle Will you kindly Let me know How you are So that I can advice you, Can you Write By Return and Just state How you feel, &c.

& Oblige
yours truly
J. LESLIE.

Kindly take Enclosed as Before

Analysis of the FLUID contained in the three Bottles sent by "PROFESSOR" LESLIE.

This is an opalescent, slightly yellow fluid, in appearance not unlike weak tea. It is safe to say that it contains more than 98 per cent. of water. On boiling a strong smell of senna was evolved, and satisfactory evidence of senna was obtained on applying certain chemical tests. Ether extracted a trifling quantity of material which had a characteristic smell unmistakeably like rue. The results of the examination in short suggest that this liquid is senna and rue tea.

The specific gravity of the fluid was 1004, the amount of extractives was 0·31 per cent., of which 0·07 per cent. was due to alkaline carbonate and 0·21 per cent. to organic substances.

On burning the extractive matters a smell exactly like the fumes of a leaf extract when smouldering was evolved.

The liquid after a few days developed a mould after the manner of infusions of the kind indicated by the analysis.

It apparently contained no aloes.

Extracts with chloroform yielded no specific substance—i.e., of the nature of an alkaloid or bitter.

No difference could be traced in the composition of all three specimens except that the third one sent contained peppermint oil. This specimen was therefore more stable than the rest owing to the antiseptic action of the peppermint.

We shall continue next week an analysis of various pills and potions received in the course of this inquiry.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE fortieth sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Dec. 12th. The Commissioners present were Lord Llandaff, Sir John Dorington, Sir George Barclay Bruce, Major-General Scott, Mr. de Bock Porter, and Mr. Robert Lewis. Mr. Cripps, Q.C., was also present for a short time. The first part of the sitting was occupied by the cross-examination of Mr. Middleton which was concluded. The only other witness examined was Mr. Walter Hunter who put in a large number of tables giving his estimates of the comparative cost of an increased supply of water from Wales and from the Thames. Mr. Hunter's tables were not prepared on actually the same lines as those of Mr. Middleton. The witness's chief contention was that 100 million gallons a day was a sufficient amount of water to flow over Teddington weir and he gave it as his opinion that no harm would be done if the metropolitan water companies were allowed to take all in excess of that amount.

In answer to the CHAIRMAN Mr. HUNTER said that he was a member of the Institute of Civil Engineers and of the Institute of Mechanical Engineers; that he was the engineering director of the Grand Junction Waterworks Company and joint engineer of the Staines Reservoirs Joint Committee; that he was in practice as a civil engineer in Westminster and was formerly a member of the London County Council when he represented that body on the Lee Conservancy Board. In conjunction with Mr. Alexander Fraser he was the author of a memorandum which was laid before Lord Balfour's Commission. This memorandum recommended the Staines reservoir scheme and received the approval of Sir Frederick Bramwell and of Mr. Thomas Hawkesley. The principle of the scheme which he had recommended was that water from the Thames should be taken when there was an abundant flow and used as occasion required. The witness said that in his opinion it would be less costly to increase the amount of storage capacity and take the water from the Thames than it would be to bring up a new supply from Wales. The question of the relative cost of these two schemes would naturally not be affected whether the undertakings were purchased and put in the hands of a single authority or whether they remained as they are at present in the hands of the water companies. The witness said that in his opinion it was not necessary to allow flood water to run to waste for so long a period as fifteen days; he believed that the suggestion that no water should be taken after a flood for this lengthened period was due to a communication received from the Local Government Board. He did not know whether the communication was made by Major-General Scott or by some other authority on the Local Government Board. The communication was not an official one but was given in a private letter to his colleague Mr. Fraser. In his own opinion the witness said it would be sufficient to avoid taking flood water for a period of two days, but in deference to the general opinion that a longer period was necessary he had taken six days as the basis for his calculations. Sir William Crookes and Professor Dewar (who are employed by the metropolitan water companies) said in their report for November, 1898, that the bacteriological quality of the London water does not depend upon the rejection or the use of flood water but upon the efficiency of filtration. The witness contended that as much water as possible should be taken during periods of flood so that the flow of the river might be equalised. In his opinion water of dark colour like that supplied to Manchester would not be popular in London and he thought that if it were supplied it would give rise to a popular outcry. The CHAIRMAN suggested that the peaty colour of the water caused no harm and Sir JOHN DORINGTON suggested that the colour of water might be a matter of taste. The witness contended that a flow of 200 million gallons of water daily over Teddington weir was not required.

In answer to Major-General SCOTT he declined to give an opinion as to the result a lessened flow would have with regard to the growth of weeds in the bed of the upper river.

Sir JOHN DORINGTON suggested that the river as a pleasure resort would be less pleasant if the river were sluggish, although he admitted that it would be easier in that case to row up stream. The witness contended that a reduction of the flow of the river from 200 million gallons to 100 million gallons daily would make no practical difference with regard to the scour produced by the passage of water in the lower reaches. Since the early part of the present century the scour of the river had been greatly increased, first by the removal of Old London Bridge and of late years by the Thames Embankment. During last summer the flow over Teddington weir had been reduced to 42 million gallons daily but he had not heard of any complaints.

Mr. DE BOCK PORTER asked the witness whether the companies should in his opinion forego the right they had of taking water when by doing so they reduced the flow to a less amount than 100 million gallons daily. The witness replied that he did not think the companies would forego anything.

With regard to the diminished flow of water this summer the CHAIRMAN said that they had it in evidence that penny steamers had gone aground and he gave it as his opinion that that must have been inconvenient for them.

At this point a number of tables were put in although the CHAIRMAN remarked that he thought that they had already enough tables for an ordinary mind.

In answer to the CHAIRMAN the witness said that the estimates which he gave in his tables with regard to the cost of the Welsh scheme were made from analogy and not as the result of a survey. The witness admitted that he had not seen the country and the CHAIRMAN asked him if he were not tendering unreliable material to replace "good material" which had been supplied as the result of actual surveys.

The forty-first sitting of the Royal Commissioners was held at the Guildhall, Westminster, on Dec. 13th. The Commissioners present were Lord Llandaff, Sir John Dorington, Sir George Barclay Bruce, Major-General Scott, Mr. de Bock Porter, and Mr. Robert Lewis. The first part of the sitting was occupied by the cross-examination of Mr. Hunter and the latter part of the evidence of Sir Frederick Bramwell.

Digitized by Google

Sir FREDERICK BRAMWELL, in answer to the CHAIRMAN, said that in his opinion neither the London County Council nor a body of experts would manage the London water-supply better than the present companies. He was opposed to compulsory purchase of the water companies' undertakings. In the purchase price an allowance would have to be made for progressive increase of dividends. In the case of the West Middlesex Company the witness admitted that of course there could be no increase as the company was already paying at the full maximum amount allowed by Parliament. He did not think that the values of the undertakings could be properly determined on the basis of the present dividends in those cases in which companies were not paying the full amount allowed.

In answer to the CHAIRMAN he admitted that in the case of a company such, for example, as the East London in which it would be necessary to increase the amount of storage reservoirs and in which therefore an unremunerative outlay must necessarily be incurred—such a fact would depreciate the value of the undertaking. The witness, however, contended that if it appeared that a company would in course of time extend its business he thought that the possible future dividends should be taken into account.

The CHAIRMAN suggested that surely in the case, for example, of a railway which was purchased it would not be fair for the company to say that they might be able to extend the line in different directions and that this would bring in a large increase of dividends and that the present undertaking was worth more on that account. The witness thought that an arbitrator would have to listen to such a suggestion, but he was not prepared to say what importance he would attach to it.

The CHAIRMAN suggested that there appeared to be an opinion that the East London Company had not displayed due foresight in providing a sufficient storage amount of reservoirs. The witness pointed out that Professor Stuart in the House of Commons had violently opposed the scheme for the increase of the storage reservoirs and that he had in making that speech represented himself as speaking the voice of the London County Council. One learned counsel proposed to read the speech but the Commissioners did not wish to hear it. The witness thought that the provisions of the sinking clause first introduced by Lord Claud Hamilton and which was now always introduced into Bills for raising capital became rather unfair to the companies when the money was raised rather for the improvement of the undertakings than for the benefit of the shareholders of the company.

Towards the end of the sitting some questions were asked with regard to control and the witness said that in his opinion the water examiner, Major-General Scott, ought to be allowed to visit the companies' works as a matter of right and not simply as a matter of courtesy. The witness, however, thought that officials of the County Council, with the exception possibly of their medical officer of health, ought not to be allowed to overrun the private works of the companies. In support of this opinion he related a case of a very filthy representative of a local authority in the country who was sent to take a specimen of the water and he thought that such a person would not be likely to have the necessary skill to take a sample of water. This incident, the witness appeared to think, bore on the question of visitations of the companies' works by county councillors. The witness said that in his opinion the Acts of 1847, 1852, 1871, and 1897 afforded ample protection to the water consumers of London.

The CHAIRMAN remarked that it had unfortunately been strongly borne in upon them that no one apparently paid any attention to ensure the protection which these various enactments were intended to supply to the water consumers of London.

The next sitting of the Royal Commissioners will take place on Monday next, Dec. 19th, and the CHAIRMAN intimated that another sitting would take place on the following day if they could ensure a continuous supply of witnesses.

ELECTRIC LIGHTING AT CARDIFF.—The arc lamps in St. Mary-street and also the incandescent lights in the town-hall went out recently at a time when the stipendiary magistrate was trying a case, the coroner's court was sitting, and the municipal offices were busy. The police-court case was adjourned, but the coroner and jury resorted to candles until the electric light was again available.

THE PROPOSED SCHOOL OF TROPICAL MEDICINE.

THE following letter has been addressed to the *Times* and should go far to instruct the general public, as we have taken pains to inform the medical profession, upon the merits of the scheme which has been put forward for the foundation of a school of tropical medicine:—

To the Editor of the TIMES.

SIR,—The proposed scheme for affording additional instruction in tropical medicine has attracted attention to a subject with which the medical profession entirely sympathise. That physicians and surgeons who propose to practise in hot climates should have an opportunity afforded them for the special study of tropical diseases is no doubt most desirable not only on the ground of humanity, but also as a duty to British subjects resident in the tropics. Having regard, however, to the scheme as detailed in the Colonial Office circular, dated the 9th ult., there are several points bearing on its practicability and prospect of success which require careful consideration before it is finally adopted.

The scheme is very costly. It is estimated that the initial outlay will be £16,460 and that the annual cost of maintenance will be £3000. Towards the first item the Colonial Office contributes £3500, and it is estimated that the Colonial Medical Service candidates will contribute £1000 to the latter. This leaves a capital sum of £12,960 and £2000 per annum to be raised from the public. Fees from students would partly defray the yearly expenditure, but it is doubtful whether such sums can be procured from either or both sources.

A memorandum and circular are now being circulated by the Seamen's Hospital Society which state that the school is intended for medical graduates only. Of these candidates for the Colonial Medical Service will form a part and it is anticipated that missionary societies, trading corporations, and private practitioners connected with the tropics will avail themselves of the opportunities offered by the proposed school. The number of students expected to be forthcoming is not stated, and it is well to consider whether additional facilities to those already existing are required before incurring the contemplated heavy expenditure.

The candidates for the Colonial Medical Service could be instructed at Netley where the Royal Victoria Hospital affords more material for clinical instruction than can be obtained anywhere else and has a staff of teachers practically acquainted with tropical diseases as well as an excellent bacteriological laboratory. There seems to be no reason why these candidates should not go through a four months' residential course at Netley and obtain the advantages which its hospital and school now afford to candidates for the Army and Indian Medical Services. It appears to us that candidates for the Colonial Medical Service might fairly be required to pass through this course as a qualification for appointment.

Medical men connected with missionary societies and trading corporations, along with those who in a private capacity propose to practice in the tropics, have open to them for the special study of these diseases the London and provincial schools of medicine where the subject is already taught. Many of these are provided with bacteriological laboratories and all that is required for academic teaching. For clinical work the material afforded by the *Dreadnought* and its Branch (the former is much more accessible) is available for those residing in London, while those resident in the provinces have valuable opportunities in this respect at such ports as Liverpool, Newcastle, Bristol, and other places. It must not be overlooked that the diseases of hot climates are included in the lectures on the practice of medicine given at every medical college and school in the kingdom. It appears therefore that sufficient means of instruction already exist and the large initial outlay and costly maintenance of the proposed school and hospital are consequently uncalled for.

In the published correspondence between the honorary medical staff and the committee of management of the *Dreadnought* Hospital it is stated in Mr. Michelli's letter, dated July 14th, that "the committee will propose, as far as possible to concentrate cases of tropical disease at the teaching centre." We are informed that

Digitized by Google

this has been already done to some extent, for the Albert Docks branch has detained patients who were originally intended to be passed on to Greenwich and the parent institution has therefore been depleted in order to feed its branch. This seems to be very undesirable in the case of the *Dreadnought* with its past traditions, and the more so because the cases of tropical disease in that hospital have been used already for teaching purposes in connexion with one of the London schools.

It is, we think, unfortunate that the Secretary of State for the Colonies did not consult such an authority as the Royal College of Physicians as to the best method of giving effect to the scheme before it was made public, and it is much to be regretted that the Committee of Management of the Seamen's Hospital Society neglected to consult their senior visiting medical staff on a matter so seriously affecting themselves and the usefulness of the hospital at Greenwich.

We are, Sir, your obedient servants,

WM. ROBERTS, M.D., F.R.S.
DYCE DUCKWORTH, M.D., LL.D.,
Physician and Lecturer on Medicine, St. Bartholomew's Hospital.
J. FAYRER, M.D., F.R.S.,
Consulting Physician, Charing-cross Hospital.
WILLIAM M. ORD., M.D. Lond., F.R.C.P.,
Consulting Physician to St. Thomas's Hospital.
W. S. CHURCH, M.D., F.R.C.P.,
Senior Physician, St. Bartholomew's Hospital.
W. R. GOWERS, M.D., F.R.S.,
Consulting Physician, University College Hospital.
I. BURNEY YEO, M.D., F.R.C.P.,
Senior Physician to King's College Hospital and Professor of Medicine in King's College.
FREDK. T. ROBERTS, M.D., F.R.C.P.,
Professor of Medicine at University College; Physician to University Hospital.
A. ERNEST SANSOM, M.D., F.R.C.P.,
Physician to the London Hospital and Lecturer on Clinical Medicine to the London Hospital.
THOMAS BUZZARD, M.D., F.R.C.P.,
Physician to the National Hospital for the Paralysed and Epileptic.
W. B. CHEADLE, M.D., F.R.C.P.,
Senior Physician to St. Mary's Hospital and Lecturer on Clinical Medicine.
THOS. WHIPHAM, M.D., F.R.C.P.,
Physician to St. George's Hospital.
W. CAYLEY, M.D., F.R.C.P.,
Physician to the Middlesex Hospital.
G. FIELD BLANDFORD, M.D., F.R.C.P.,
Lecturer on Psychological Medicine, St. George's Hospital.
F. DE HAVILLAND HALL, M.D., F.R.C.P.,
Physician to the Westminster Hospital.

Dec. 14th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Dec. 8th, the President, Sir WILLIAM MACCORMAC, Bart., being in the chair.

A report was read from the Board of Examiners in Dental Surgery recommending the Council to express their approval of the recommendations of the General Medical Council as to the course of study and examination for Licences in Dental Surgery, as the recommendations appeared to be in all important particulars similar to the regulations of the College. The Board did not advise the issue of schedules defining the range of examination in anatomy and surgery, as in their opinion it would probably lead to a system of cramming. The report was adopted.

The Council also adopted a report from the Committee of Management. It contained the synopsis of practical pharmacy based on the new Pharmacopœia and intended to come into force on May 1st, 1899, it recommended that the examination in materia medica and pharmacy applicable only to candidates under the old regulations should be conducted in future in *viva voce* only on account of the small number of candidates now eligible under those regulations; and the committee requested that in consequence of a desire expressed by the teachers and examiners in physiology that there should be an examination in practical physiology they might be empowered to consider the question, to take the opinions of the several medical schools, and to report to the College on a future occasion.

The Council having been informed that the name of a Member of the College had been erased from the Medical Register called upon the Member to show cause why he should not be removed from being a Member of the College.

A letter was read from Sir William Turner, President of the General Medical Council, enclosing a copy of two clauses drafted with the object of amending the Medical Acts so as to prevent persons whose names have been erased from the Medical Register for a criminal offence or for professional misconduct from using any title, diploma, or degree so long as the erasure remains in force, and inquiring whether such clauses are approved by the Council of the College. The matter was referred to the Discipline Committee.

The PRESIDENT reported the proceedings at the annual meeting of Fellows and Members and stated that in addition to 15 members of the Council there were present 17 Fellows and 75 Members.

The first resolution which was carried at that meeting and which requested the Council to attempt to remedy the notorious abuses existing in connexion with medical practice, was referred to the Discipline Committee.

The second resolution which requested that the Members should be allowed to have some share in the election of the governing body was considered and it was resolved that "The Council do not consider it either necessary or desirable to reopen the question of the representation of Members on the Council after the large share of attention which the Council have of late given to the matter and after the result of the recent canvass of the Fellows."

The third resolution which requested the Council to express its disapproval of Fellows and Members of the College acting as the paid officials of any association which employs professional advertisements was referred to the Discipline Committee.

The fourth resolution which referred to the granting to the Members permission to wear a gown was referred to the Committee for General Purposes.

A letter was read from the Board of Trade stating that owing to the recent revision of the British Pharmacopœia the medical scales issued by them for merchant and passenger ships will require to be amended, and asking the Council to nominate two representatives, as they did in 1888, to serve on a committee to be appointed for the purpose of revising the scales.

Mr. Alfred Willett and Mr. Richardson Cross were nominated as representatives.

The SECRETARY laid before the Council an invitation from the Imperial Military School of Medicine at St. Petersburg asking the College to send representatives to the celebration of its centenary at St. Petersburg on Dec. 18th, 1898. Two members were nominated.

The PRESIDENT reported the delivery of the Bradshaw Lecture by Mr. T. Pickering Pick on Dec. 7th, the subject being "The Union of Wounds." The best thanks of the Council were given to Mr. Pick for his lecture and he was requested to publish it.

A letter was read from Mr. THOMAS BRYANT reporting the proceedings of the General Medical Council and he received the thanks of the Council for his services as the representative of the College.

Mr. HENRY MORRIS moved:—

That a committee be appointed to consider and report whether any change, and if so what change, should be made (to the advantage both of the College and of the candidates) in the conditions under which candidates are admitted to the examinations for the Fellowship of the College.

A committee for this purpose was appointed.

PUBLIC VACCINATORS AND THE NEW VACCINATION ACT.

PUBLIC VACCINATORS AT UPPINGHAM.

THE public vaccinators of the Uppingham Union held a meeting at the house of the senior practitioner on Dec. 7th, and having agreed upon the terms which they considered satisfactory under the provisions of the new Vaccination Act

Digitized by Google

met the guardians and obtained the following fees:—General Order Vaccination Acts 1867–1898, Amended Regulations: Page 14, Section 1, 2*s.* 6*d.*; Page 15, Section 2, 10*s.*; Section 3, 5*s.*; and in the event of any child having been successfully vaccinated and requiring, as the result of such vaccination, further attendance after the visit of inspection a fee of 2*s.* 6*d.* for each visit, to include medicine. The public vaccinators to pay all postage. The guardians met their officials in a business-like manner and gave a very courteous hearing to their side of the case.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual general meeting of constituents was held on Monday, Dec. 12th, at the Mansion House, when the Right Hon. Sir JOHN VOCE MOORE, Lord Mayor, President and Treasurer of the Fund, presided.

The Bishop of STEPNEY proposed the adoption of the annual report (details of which will be found in THE LANCET of Dec. 3rd, p. 1501). In doing so he said that everyone felt that this Fund was one of the most business-like funds that we have in London. From his experience it was also the one which appealed most to the working men of London. Over £40,000 had been collected this year but he hoped that everyone would strive to do their best to increase that sum next year.

The Rev. W. H. HARWOOD, in seconding the motion, said that in making his appeal to his congregation he had followed the example of Canon Fleming and had called attention to the collection previously to its being actually made.

The report having been adopted, Mr. RICHARD B. MARTIN, M.P., moved that the Laws of the Constitution be continued, and took occasion to appeal to ministers of all denominations not to allow any part of the collections made on Hospital Sunday to be put aside for other purposes.

Sir EDMUND HAY CURRIE seconded the motion which was subsequently adopted. Some discussion, however, took place, Mr. FREDERICK NORTON asking that the proportion of the collection given to dispensaries should be increased. The Prince of Wales's Fund did not include dispensaries in its distribution, and consequently the hospitals received awards from both funds and the dispensaries from only one.

The Earl of STAMFORD, referring to the appointment of an inquiry officer in the out-patient department of hospitals, suggested that the inquiry officer should not only weed out those applicants who were not entitled to hospital charity but should, he said, be qualified to see that patients if they required treatment got it elsewhere.

Dr. GLOVER expressed his sympathy with the remarks of Mr. Norton. He had himself noticed the very attenuated amount given to dispensaries, and although he did not think it desirable to propose an amendment he thought the matter should be taken notice of by the Council.

Ex-Sheriff COOPER and the Rev. Prebendary WHITTINGTON respectively proposed and seconded a motion to the effect—

That the Council for the year 1898 be re-elected for the year 1899 with the Right Honourable the Earl of Aberdeen, Lord Lister, Sir Horatio D. Davies, K.C.M.G., M.P., and the Rev. Walford Green to fill vacancies.

This was carried and

Canon FLEMING proposed:—

That June 11th be fixed for Hospital Sunday of 1899 and that the cordial coöperation of all ministers of religion within the metropolitan area be again invited in the usual way.

He said he thought the Fund was educating more and more the public of all classes to see the necessity for and the needs of hospitals. He hoped that the day was far off when voluntary philanthropy would be superseded by State aid.

The Rev. Canon GRAHAM seconded the proposal which was carried.

Mr. COHEN suggested that much good might result if the Lord Mayor sent a letter to the proprietors of large hotels some time before Hospital Sunday asking them to inform their patrons of the date of Hospital Sunday and to make arrangements if possible for collections in such hotels.

The Rev. Dr. HODSON said that the collection would greatly benefit if ministers sent out post-cards to their congregations before the actual day of collection.

The Right Hon. W. LIDDERDALE proposed a vote of thanks to the Lord Mayor, which was seconded by the Rev. Prebendary KITTO and carried with acclamation.

In his reply the LORD MAYOR said he trusted that the highest hopes of the well-wishers of the Metropolitan Hospital Sunday Fund would be realised in his year of office and that he would do his utmost for the good of the Fund.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Sanitary Administration in the County Borough of West Bromwich, by Dr. G. S. BUCHANAN.[1]—This report might be fittingly entitled "West Bromwich revisited," since it relates to a second inspection of the district made by Dr. Buchanan with a view to ascertain what steps have been taken to carry out the recommendations accompanying his first report in February, 1896, relative to the condition of the borough and the prevalence of enteric fever therein. As is not unusual in the case of insanitary districts, such as West Bromwich, the town council, in response to communications addressed to them by the Local Government Board as to what action they were taking in reference to the inspector's report, appear to have written evasive and unsatisfactory letters. The Board therefore directed Dr. Buchanan to revisit West Bromwich and to report as to the action of the town council. The district in question is one of those in which the inhabitants have a custom of storing up their excrement and house refuse in capacious covered privy-middens sunk below the ground level and so constructed as to allow the escape of their liquid contents. These middens are often dangerously situated near doors and windows and it is hardly to be wondered that enteric fever should from time to time prevail. The action of the town council prior to 1896 had been half-hearted and unsatisfactory and Dr. Buchanan found it necessary to insist that more attention should be bestowed on almost every sanitary subject other than water-supply and main sewerage. It cannot be said that in the period of nearly three years which has elapsed between the inspector's two visits that the town council have made astounding progress, but they have paid attention to insanitary premises and have taken some action as to houses unfit for habitation. So, too, in yard-paving and drainage advance has been made, though makeshift work seems to have been well to the front in this particular; and in respect to middens and privies the town council do not seem to have received much encouragement from the stipendiary magistrate whose decisions are apparently somewhat retrograde in tendency. It is unsatisfactory to learn that the cowsheds are neglected and that certain of the milkshops are in a far from desirable condition. Dr. Buchanan has certainly not dealt hardly with the very obvious shortcomings of the West Bromwich Town Council and it is to be hoped that they will show their appreciation of his consideration by carrying out his recommendations and by proving themselves more worthy of the dignity of a county borough.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6691 births and 3835 deaths were registered during the week ending Dec. 10th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 17·0 to 19·1 per 1000, declined again last week to 17·8. In London the rate was 16·7 per 1000, while it averaged 18·5 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·4 in Derby, 12·6 in Croydon, 13·2 in Huddersfield, and 13·6 in West Ham; the highest rates were 22·0 in

Liverpool, 23·0 in Swansea, 23·2 in Sunderland and 27·2 in Bolton. The 3835 deaths in these towns included 399 which were referred to the principal zymotic diseases, against 365 and 426 in the two preceding weeks; of these 32 resulted from diphtheria, 84 from measles, 75 from "fever" (principally enteric), 59 from whooping-cough, 56 from diarrhœa, 32 from scarlet fever, and 1 from small-pox. No death from any of these diseases were recorded last week in Plymouth or in Wolverhampton; in the other towns they caused the lowest death-rates in Croydon, Bradford, and Derby, and the highest rates in Portsmouth, Swansea, Nottingham, Bolton, and Preston. The greatest mortality from measles occurred in West Ham, Nottingham, Manchester, and Bolton; from whooping-cough in Bristol, Swansea and Preston; and from "fever" in Bolton and Sheffield. The mortality from scarlet fever showed no marked excess in any of the large towns. The 92 deaths from diphtheria included 43 in London, 9 in Leeds, 7 in West Ham, 5 in Swansea, 5 in Sheffield, 4 in Portsmouth, and 4 in Liverpool. One fatal case of small-pox was registered in Liverpool, but not one in any other of the thirty-three large towns; and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of last week was 3090, against 3259, 3162, and 3142 on the three preceding Saturdays; 276 new cases were admitted during the week, against 319, 234, and 264 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 280 and 340 in the two preceding weeks, declined again last week to 295, and were 139 below the corrected average. The causes of 33, or 0·7 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Salford, Bradford, Leeds, and in fifteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·7 and 21·0 per 1000 in the two preceding weeks, was again 21·0 during the week ending Dec. 10th, and was 3·2 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Leith, and 14·5 in Paisley, to 23·0 in Aberdeen and in Greenock, and 24·5 in Edinburgh. The 633 deaths in these towns included 18 which were referred to diarrhœa, 16 to whooping-cough, 12 to measles, 11 to "fever," 10 to scarlet fever, and 4 to diphtheria. In all, 71 deaths resulted from these principal zymotic diseases, against 73 and 83 in the two preceding weeks. These 71 deaths were equal to an annual rate of 2·4 per 1000, which was 0·5 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased from 9 to 21 in the three preceding weeks, declined again to 16 last week, of which 8 occurred in Glasgow and 3 in Edinburgh. The 12 deaths from measles showed a decline of 7 from the number in the preceding week, and included 5 in Glasgow and 3 in Edinburgh. The deaths referred to different forms of "fever," which had declined from 16 to 10 in the four preceding weeks, were 11 last week, of which 6 occurred in Glasgow, 2 in Edinburgh, and 2 in Paisley. The 10 fatal cases of scarlet fever showed a further increase upon recent weekly numbers, and included 3 in Glasgow, 3 in Greenock, and 2 in Edinburgh. Of the 4 deaths from diphtheria 2 were registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 128 and 147 in the two preceding weeks, further rose to 163 last week, and were 34 above the number in the corresponding period of last year. The causes of 30, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 27·7 to 31·6 per 1000, declined again to 25·4 during the week ending Dec. 10th. During the past four weeks the rate of mortality in the city has averaged 28·9 per 1000, the rate during the same period being 17·1 in London and 22·3 in Edinburgh. The 170 deaths registered in Dublin during the week under notice showed a decline of 42 from the number in the preceding week, and included 8 which were referred to the principal zymotic diseases, against 17 and 11 in the two preceding weeks; of these, 4 resulted from "fever," 3 from whooping-cough, and 1 from diarrhœa, but not one either from small-pox, measles, scarlet fever, or diphtheria. These 8 deaths were equal to an annual rate of 1·2 per 1000, the zymotic death-rate during the same period being 1·7 in London and 2·6 in Edinburgh. The deaths referred to different forms of "fever," which had been two in each of the two preceding weeks, rose to 4 last week. The fatal cases of whooping-cough, which had been 5 and 3 in the two preceding weeks, were again 3 last week. The 170 deaths in Dublin last week included 40 of infants under one year of age and 39 of persons aged upwards of sixty years; the deaths of infants showed a further increase, while those of elderly persons showed a further decline from recent weekly numbers. Seven inquest cases and 8 deaths from violence were registered; and 68, or more than a third, of the deaths occurred in public institutions. The causes of 16, or nearly 4 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING NOVEMBER, 1898.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during November in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 10·8 per 1000 of the population, estimated at 4,504,766 persons in the middle of this year. In the three preceding months the rates had been 6·5, 8·9, and 11·5 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Kensington, St. George Hanover-square, St. James Westminster, St. Martin-in-the-Fields, Strand, and St. Olave Southwark; while they showed the largest excess in Fulham, St. Luke, St. Saviour Southwark, Bermondsey, Woolwich, and Plumstead. Only one case of small-pox was notified in London during November (in Battersea sanitary area), and no small-pox patients were under treatment last month in any of the Metropolitan Asylum Hospitals. The prevalence of scarlet fever in London showed a decline from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Hammersmith, Fulham, St. Pancras, Islington, Stoke Newington, St. Luke, Greenwich, and Plumstead. The Metropolitan Asylum Hospitals contained 3090 scarlet fever patients at the end of November, against 2207, 2425, and 2977 at the end of the three preceding months; the weekly admissions averaged 288, against 202, 270, and 350 in the three preceding months. The prevalence of diphtheria in London during November almost corresponded with that recorded in the preceding month; this disease was proportionally most prevalent in Holborn, St. Luke, St. Saviour Southwark, Newington, Bermondsey, Battersea, Lewisham, and Woolwich sanitary areas. There were 1269 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of November, against 865, 1024, and 1182 at the end of the three preceding months; the weekly admissions averaged 172, against 107, 163, and 172 in the three preceding months. The prevalence of enteric fever in London showed a further increase upon that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Marylebone, St. Pancras, St. Giles, City of London, Shoreditch, and St. George-in-the-East. The Metropolitan Asylum Hospitals contained 286 enteric fever patients at the end of November, against 118, 155, and 223 at the end of the three preceding months; the weekly admissions averaged 45, against 21, 28, and 41 in the three preceding months. Erysipelas was proportionally most prevalent in St. Giles, St. Luke, Bethnal Green, Whitechapel, St-George-in-the-East, and Mile End Old Town sanitary areas. The 40 cases of puerperal fever notified in London during November considerably exceeded the number recorded in any recent month, and included 4 in Camberwell, 3 in Hackney, 3 in Lambeth, and 3 in Greenwich sanitary areas.

The mortality statistics in the table relate to the deaths of

persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Dec. 3rd, the deaths of 7049 persons belonging to London were registered, equal to an annual rate of 16·3 per 1000, against 20·7, 21·0, and 17·3 in the three preceding months. The lowest death-rates in the various sanitary areas were 9·1 in Hampstead, 11·3 in Plumstead, 11·5 in Wandsworth, 11·6 in Lee, 12·0 in Stoke Newington, and 12·2 in Lewisham; the highest rates were 21·0 in Bermondsey, 21·1 in Bethnal Green, 21·8 in St. Martin-in-the-Fields, 22·1 in Clerkenwell, 24·0 in St. George Southwark, 24·4 in London City, and 27·2 in St. Luke. During the five weeks of November 647 deaths were referred to the principal zymotic diseases in London; of these, 110 resulted from measles, 58 from scarlet fever, 182 from diphtheria, 81 from whooping-cough, 126 from enteric fever, and 90 from diarrhœa. These 647 deaths were equal to an annual rate of 1·5 per 1000; among the various sanitary areas the lowest zymotic death-rates were recorded in St. George Hanover-square, Westminster, St. James Westminster, Hampstead, Stoke Newington, Strand, Lewisham, and Plumstead; and the highest rates in Clerkenwell, St. Luke, City of London, Bethnal Green, St. Saviour Southwark, and Woolwich. The 110 fatal cases of measles were as many as 182 below the corrected average number in the corresponding periods of the ten preceding years; this disease showed the highest proportional fatality in Clerkenwell, St. Luke, Shoreditch, Bethnal Green, Whitechapel, and St. Saviour Southwark sanitary areas. The 58 deaths referred to scarlet fever were only half the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Hammersmith, Fulham, and St. Luke. The 182 fatal cases of diphtheria were 73 below the corrected average number; this disease showed the highest proportional fatality in St. Pancras, St. Luke, City of London, Bethnal-green, Mile End Old Town, St. Saviour Southwark, Bermondsey, and Woolwich sanitary areas. The 81 deaths from whooping-cough were 56 below the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Holborn, St. George-in-the East, Newington, and Wandsworth. The 126 deaths referred to enteric fever were 41 above the corrected average number; this disease showed the highest proportional fatality in Fulham, City of London, Limehouse, St. Saviour Southwark, and Woolwich sanitary areas. The 90 fatal cases of diarrhœa were slightly below the corrected average number. In conclusion, it may be stated that the aggregate mortality in London last month from these principal zymotic diseases was more than 33 per cent. below the average.

Infant mortality in London during November, measured by the proportion of deaths of children under one year of age to registered births, was equal to 133 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Hampstead, Stoke Newington, St. Giles, Lewisham, Woolwich, and Lee; and the highest rates in St. James Westminster, St. Martin-in-the-Fields, Holborn, St. Saviour Southwark, St. Olave Southwark, St. George Southwark, and Rotherhithe.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

STAFF-SURGEONS Edward G. Swan and John Otley have been placed on the Retired List.

The following appointments are announced:—Fleet-Surgeon Standish T. O'Grady to Yarmouth Hospital. Staff-Surgeon Herbert P. Shuttleworth to the *Cambridge* temporary. Surgeons: William H. Pope to the *Thunderer* and William J. Colborne to the *Victory* for disposal.

ARMY MEDICAL STAFF.

Colonel William S. M. Price, R.A.M.C., to be Surgeon-General, vice A. A. Gore, retired.

ROYAL ARMY MEDICAL CORPS.

Colonel Frederick B. Scott, C.M.G., is placed on retired pay. The under-mentioned Lieutenant-Colonels to be Colonels:—Alexander W. Duke, vice W. S. M. Price and James M. Beamish, vice F. B. Scott, C.M.G.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the retirement from the Service of the under-mentioned officers:—Major-General Alfred Anderson, Madras Infantry; Lieutenant-Colonel Walter Conroy, Bengal Establishment; and Lieutenant-Colonel Malachi O'Dwyer, Bengal Establishment.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant E. P. A. Mariette resigns his commission.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Northumberland Fusiliers: David Kidd Muir to be Surgeon-Lieutenant. 1st Middlesex (Victoria and St. George's): Surgeon-Captain F. E. Fenton to be Surgeon-Major. 2nd Volunteer Battalion Highland Light Infantry: Surgeon-Lieutenant W. F. Macdonald resigns his commission.

MENTIONED IN DISPATCHES.

In a dispatch from Major-General Lord Kitchener of Khartoum, G.C.B., K.C.M.G., Sirdar of the Egyptian Army, the names of the following medical officers who have distinguished themselves during the recent operations in the Soudan are mentioned:—Lieutenant-Colonel J. A. Clery, R.A.M.C.; Lieutenant-Colonel N. Leader, late R.A.M.C.; Major G. D. Hunter, D.S.O., R.A.M.C.; and Captain C. C. Flemming, R.A.M.C.

SURGEON MAILLARD, V.C.

Surgeon W. J. Maillard, of the *Hazard*, who, as we announced last week, has received the Victoria Cross, is the only naval medical officer in possession of the much-coveted distinction. The other officers of the Royal Navy and Royal Marines upon whom this decoration has been conferred and whose names appear in Lean's Royal Navy List are as follows:—Rear-Admiral Charles Davis Lucas, June 21st, 1854; Rear-Admiral John Bythesea, C.B., C.I.E., August 9th, 1854; Rear-Admiral Henry James Raby, C.B., June 18th, 1855; Lieutenant-Colonel George Dare Dowell, R.M.A., July 13th, 1855; Admiral of the Fleet Sir John Edmund Commerell, G.C.B., F.R.G.S., October 11th, 1855; Admiral Sir Nowell Salmon, G.C.B., A.D.C., November 16th, 1857; Israel Harding (Chief Gunner), July 11th, 1862; and Rear-Admiral Arthur Knyvet Wilson, C.B., February 29th, 1884.

RECRUITS FOR THE ARMY.

What with the growth of the empire, the rumours of war from time to time, and the unsettled state of political affairs generally the demands for the maintenance of a strong navy and army are increasing instead of diminishing. As regards the navy, it annually takes in a large number of boys who grow up on shipboard and develop into thoroughly trained and able-bodied sailors, but the army has never yet tapped the various sources of supply in the country. Several years ago we pointed out that the army might advantageously have recourse to some method for an increased enlistment of boys and the establishment of training camps for them. We are consequently glad to notice an article in our contemporary the *Army and Navy Gazette* of Dec. 10th, dealing with the subject of extending the machinery of existing State schools so that boys might be passed into the ranks of the army. We believe that a time will come when the State will recognise that it has claims in this respect in regard to youths to whom it has stood *in loco parentis* and that some system will be adopted by which the State may render their services more readily available for State purposes than at present. The subject is altogether too large to be circumscribed within the limits of a paragraph, but we think that a scheme might be devised and formulated which would prove of mutual benefit to the youths themselves as well as to the army. From a sanitary and hygienic standpoint and for improving the physique, conduct, and discipline of the boys, good would result we have little doubt.

SURGEON-GENERAL GORE.

This officer must have had long and arduous work as Principal Medical Officer of Her Majesty's Forces in India during the late tribal wars on the North-west frontier. The medical administration and arrangements for a large army in the field under such circumstances was a very responsible undertaking and our readers have been already made acquainted with the scale upon which these had to be provided. So far as we can learn they successfully withstood the severe test to which they were put during the

Digitized by Google

time General Sir W. Lockhart's forces were in the field and we therefore hope that Surgeon-General Gore's services in this respect will be recognised.

SURGEON-GENERAL W. TAYLOR, C.B.

We are glad to notice the name of Surgeon-General Taylor, C.B., of the Army Medical Service, in the list of those who have recently dined with the Queen and the Royal Family. The officer in question is a representative of a large and important branch of the army which has always done good service in the field and is still doing excellent work wherever there are British troops in various parts of the empire. It is scarcely necessary to add therefore that recognitions on Her Majesty's part of the services rendered by members of this branch of the service are very welcome and will have a good effect upon the Royal Army Medical Corps.

THE MEDICAL RESERVE OF THE FRENCH ARMY.

During the past few months upwards of 700 medical officers belonging either to the Reserve or to the Territorial Army have been put through a course of practical instruction at various centres under the supervision of experienced officers of the active army. As far as possible the convenience of individuals was consulted, the reservists being attached to corps or hospitals in the vicinity of their own residences, and during the time that they were employed they received the pay of their several grades together with certain travelling and other allowances.

PORTABLE HOSPITALS FOR THE UNITED STATES ARMY.

Sixty portable hospitals are being constructed in America for the use of the army—most of them for the troops at Porto Rico and Cuba. Each hospital—to be constructed in sections—will accommodate 40 patients; they will be raised on posts 18 in. from the ground and be made of pine and furnished with painted canvas roofs. Those intended for use in the north will have double floors and felt lining.

Major M. A. T. Collie, M.B. Aberd., of the Indian Medical Service, has been appointed to act as superintendent of Matheran. Major R. J. Baker, M.D. Dub., I.M.S., acts as superintendent to the lunatic asylum at Colaba. Major A. V. Anderson, M.B. Aberd., I.M.S., has been appointed on special plague duty in the Dharwar district.

Surgeon-General Townsend of the Umballa district has, it is believed, taken over the duties of Principal Medical Officer of Her Majesty's Forces in India from Surgeon-General Gore, pending the arrival of Surgeon-General W. Taylor, C.B.

The Queen has appointed Staff-Surgeon James Lawrence Smith, R.N., to be a Member of the Fourth Class of the Royal Victorian Order.

The following officer has qualified as interpreter in the French language:—Major J. H. Branningan, R.A.M.C.

Correspondence.

"Audi alteram partem."

THE PROPOSED SCHOOL OF TROPICAL MEDICINE.

To the Editors of THE LANCET.

SIRS,—In your issue of last week you referred to the memorandum issued by the Seamen's Hospital Society in support of the scheme proposed for the New School of Tropical Medicine as a question of general policy. I wish to examine it from another standpoint. I would incidentally remark that the memorandum and the appeal for subscriptions have not been sent to either Dr. Anderson, Mr. G. R. Turner or myself.

I am writing as the senior visiting physician of the *Dreadnought* Seamen's Hospital, whose experience of its medical work goes back more than twenty years, to the time when Sir Henry Burdett was the secretary, and is probably more complete than that of anyone living except Mr. Johnson Smith, the principal medical officer. I have continued my associations with the hospital for this long period partly from a desire to see tropical cases, partly from the old traditions of the *Dreadnought*, and partly from the opportunities it afforded me to show students and medical men specimens of tropical disease. The scheme of the committee of management of the Seamen's Hospital Society will, if carried out, effectually destroy all these.

I think that the scheme promulgated by the Committee of Management is unnecessary, most unwise, and extravagant. £13,000 in July has expanded into £16,000 in December. I shall also show that the arguments urged in its support are misleading. The scheme in the appeal of the society merely mentions a bacteriological laboratory, pathological laboratory, lectures, &c.; but the details are clearly stated in Sir Henry Burdett's letter to the *Times* of July 11th.

> Provision will be made for from twenty to twenty-five students with sleeping accommodation for about ten. There will be a fully equipped laboratory, pathological room, museum, and every other accessory calculated to make the school efficient.

Before the bacteriology of tropical medicine can be studied a general knowledge of bacteriological methods and of ordinary bacteriological diseases must first be learnt, and this can easily be obtained in the many bacteriological laboratories which now exist in London and elsewhere. The bacteriology of tropical diseases is fully taught at King's College and at Netley, and also, I suppose, at the British Institute of Preventive Medicine, and has long been so taught. A new, fully-equipped bacteriological laboratory is obviously unnecessary, and the sum for furniture, fittings, &c., for a new school of from 20 to 25 students—viz., £400—if this is to include a bacteriological laboratory and its equipments, is almost too ridiculously inadequate to be referred to.

I have carefully looked over the list of the names of the gentlemen forming the Advisory Committee, and I can only find two (excluding the chairman and deputy chairman) who can be in the slightest degree conversant with the medical work of the *Dreadnought* Seamen's Hospital. Dr. Robert Barnes was its physician in its best old days and Mr. Johnston Smith is the principal medical officer (resident). It will be news to all the others that there exists at present in the Seamen's Hospital an excellent little museum, rich in pathological material, started in the days of Busk and George Budd, and which only needs a curator for its further development. I may venture to say that with the exceptions above named no one on that Advisory Committee has ever crossed the threshold of that museum.

For the teaching of tropical medicine in London the essentials which are needed are a working laboratory for the examination of blood, sputa, excreta, &c., and an electrical room such as are in existence at every properly equipped general hospital and such as are evidently contemplated at Liverpool. These should be established at both the parent hospital and the Branch Hospital and would probably come much nearer to the modest expenditure (£350) annually required at Liverpool than to that asked for in the proposed scheme. The calculation that £1000 will be contributed annually in fees by students sent by Government is too absurd for serious attention unless the boarding and lodging of the ten students are included. But that these rooms will be constantly filled seems doubtful if the new school is so easy of access as is urged by the committee.

From these remarks on the general scheme I now pass on to a consideration of the reasons put forward in the memorandum sent out by the Seamen's Hospital Society.

1. The small number and but little variety of the cases of tropical disease treated in the society's hospitals have been clearly pointed out. We are told that the "building called the 'Dreadnought' at Greenwich which formerly was the infirmary of Greenwich Hospital is not the property of the Seamen's Hospital Society but is held by them from the Lords Commissioners of the Admiralty subject to six months' notice." This of course would obviously be a fatal objection to such a scheme as that indicated in Sir H. Burdett's letter, but considering that the society has been in possession for twenty-eight years the establishment and proper fitting up of a working laboratory and electrical room would not seriously embarrass the society's architect. Indeed, I find on page 16 of its latest report, published only this year, that since the society has occupied the premises it has much improved the building at Greenwich, a chapel has been added, and the entire drainage of the hospital has been renewed. The building of the chapel necessitated a very extensive alteration of the Somerset ward of the hospital. I think, therefore, that even on the insecure tenure put forward by the committee the necessary alterations for its proper conduct as a hospital might be carried out without incurring the displeasure of the Lords Commissioners of the Admiralty. I venture, however,

Digitized by Google

to ask, Is the whole truth disclosed, in the statement that it is held from the Lords Commissioners of the Admiralty at six months' notice? for I find the following statement in "An Account of the Origin and Progress of the Seamen's Hospital Society," published at p. 12 in the same report: "After four years' endeavours on the part of the committee to effect so desirable an object the Lords Commissioners of the Admiralty in the year 1870, under the powers afforded them by the 'Greenwich Hospital Act' of the previous session, granted the society a lease for 99 years of the infirmary, (and adjoining Somerset ward) at Greenwich Hospital at a nominal rental in view of the loan of the ship, with the attendant expense of the external repairs, fittings, and ship's stores." I leave it to the Committee of Management to reconcile the two statements.

2 and 3. These can be taken together. The relations of the Branch Hospital to the parent institution at Greenwich are sufficiently clear from a paragraph in page 11 of the committee's report for the year 1889.

> It is intended that the branch shall be in telephonic communication with the hospital at Greenwich and that the beds shall be used for the retention of urgent or special cases, all others being transferred by ambulance to Greenwich.

There is a special ambulance and a room for it at the Branch Hospital which was opened in 1890.

The manner in which this intention has been carried out since the present honorary physician was appointed in 1892 is clearly shown by the following figures. In 1892 the number of cases of malaria and dysentery—typical tropical diseases—treated at the Greenwich Hospital were respectively 65 and 36. In the past year, 1897, they have fallen to 32 and 25. If this is not a depletion and starving of the parent institution I should like to know what is. It is, moreover, admitted in the memorandum that 31 cases of malaria were treated at the Branch Hospital during the year ending Nov. 30th last. Does anyone conversant with malaria believe that the bulk of these cases could not have been taken safely and without harm across the river to the parent institution in accordance with the expressed intention of the founders who publicly appealed for subscriptions on the lines quoted above? If this policy had been honestly adhered to by the visiting physician and the present Committee of Management no such enlargement of the hospital as is now proposed would have been necessary. The ambulance does not now carry across any tropical cases except it be someone who is expected to undergo a protracted convalescence. This starving of the parent hospital of tropical diseases is rapidly bearing fruit on its medical side, for this is being more and more turned into an asylum or infirmary for chronically-diseased and incurable sailors. A census of my wards at the end of last month showed that in my 33 beds there were patients who had been there for 671, 444, 408, 266, 212, 193, 163, and 139 days, and for whom no benefit can be expected.

I would submit that it is very unfortunate that Mr. Chamberlain's most excellent wishes should not have been placed before a representative body like the Royal College of Physicians of London who would probably have nominated a committee to report on the subject. Such a committee would have carefully considered the question in its whole bearing and a comprehensive scheme would have been laid before the Right Honourable the Secretary of State for the Colonies. It must necessarily have included the work of the existing bacteriological laboratories, of the parent hospital at Greenwich as well as of its branch, and of any other medical institutions with sufficient tropical cases of disease, such as Liverpool, Leith, &c., to afford facilities for such clinical teaching. All tropical cases do not come into the Albert Docks, and other institutions should be recognised partially or entirely as teaching centres for colonial surgeons as well as the proposed new school. It would seem that Mr. Chamberlain has only had the opportunity during the inception of the scheme of obtaining the somewhat one-sided views of the medical adviser to the Colonial Office and of the Committee of Management of the Seamen's Hospital Society. The result is that he is recommended to enlarge and extend the work of the Branch Hospital, to which the colonial medical adviser is the sole physician, to build a new school there, and to make a two months' course at that school compulsory on every aspirant to the Colonial Medical Service. The injurious effects of the carrying out of the scheme on the parent hospital and other institutions have apparently but little troubled its framers.

I presume that my remembrances of these past years and my knowledge of these unpalatable facts were considered sufficient reasons why I and my colleagues were deliberately excluded from the conferences of the committee.

Another instance of disingenuousness is shown in the appeal for funds and should be mentioned. In the face of our published correspondence they actually circulate this paragraph:—

> The educational body of the school will include not only members of the staff of the Seamen's Hospital Society, on which are to be found men who have themselves practised in the tropics, but.....

Two members only of the medical staff—Dr. Manson and Dr. John Anderson—have practised in the tropics. Dr. Manson may be the educational staff. I have yet to learn that Dr. Anderson has signified his willingness to join. Can any statement be more misleading? Apologising for the length of this letter which, I hope, clearly explains the situation,—I am, Sirs, yours faithfully,

JOHN CURNOW, M.D., F.R.C.P. Lond.,
Senior Visiting Physician to the Seamen's *Dreadnought* Hospital.
Wimpole-street, W., Dec. 12th, 1898.

We have received from the Secretary of the Seamen's Hospital Society a copy of a letter addressed by him to Sir William Broadbent which we print below.

Dreadnought Seamen's Hospital, Greenwich, S.E.,
Dec. 14th, 1898.

DEAR SIR WILLIAM BROADBENT,—I have to acknowledge the receipt of your letter of Dec. 7th. I understood it to have been written as an official communication and therefore brought it before the Committee of the Seamen's Hospital Society at their meeting on Dec. 9th.

You state that the action of the Committee "prevented certain aspects of the question from being brought to the notice of the Secretary of State and made the data on which he based his judgment imperfect and one-sided" and that thus "his approval was obtained under false pretences." This statement the Committee maintain has no foundation. There has certainly been no false pretence and the use of such a term is indefensible. The Committee believe that all aspects of the question have been put before the Secretary of State and fully considered by him. If in your view this is not so the Committee cannot doubt that Mr. Chamberlain is still open to consider the matter from any fresh aspect in which it can be put before him. You further state broadly that the Committee have made a suggestion falsely in saying that the visiting staff have been invited to coöperate. The Committee much regret that you should have permitted yourself to make such a statement and they protest not only against the language but against so strained an interpretation of the memorandum. The correspondence which the *Dreadnought* visiting staff have published shows clearly at what stage they were asked to coöperate and nothing has been written in the memorandum to lead to the conclusion that they were invited to coöperate at an earlier date than is disclosed by the correspondence. Whether the invitation when sent was an insult or not is a question on which the public will form their own opinion. It was not so intended by the Committee and they do not gather that the visiting staff have so viewed it.

The Committee observe that you object to the omission from Sir Henry Burdett's letter, as issued with the memorandum, of the passage against which the *Dreadnought* visiting staff so strenuously protested. The letter was reprinted in such a form as to show that a passage had been omitted. The Committee recognised that after the protest of the visiting staff the paragraph objected to must not be republished, but they saw no occasion to abstain from publishing the rest of the letter. We can hardly suppose that the visiting staff will join in your protest against the omission of the paragraph in question.

The Committee cannot but feel astonishment at a charge of such dishonourable acts as "suppression of truth material to the issue and suggestion of what is calculated to mislead" being made against them by a leading physician. Such charges as these are most regrettable and unfounded and, the Committee fear, will not tend to the amicable adjustment of the difficulty which has arisen and which the Committee greatly regret and are anxious to do everything in their power to remove.

Believe me to be, yours faithfully,

P. MICHELLI, Secretary.
Sir Wm. Broadbent, Bart., M.D., F.R.C.P., F.R.S., &c.,

WHAT IS TABES MESENTERICA IN INFANTS?

To the Editors of THE LANCET.

SIRS,—The subject of tuberculosis, especially its prevention, is just now being brought prominently before the profession and the public; it is therefore of the utmost importance that the figures on which are based the arguments for preventive measures should be as accurate as possible. As you observe in your leading article of Dec. 3rd Sir Richard Thorne in the recent Harben Lectures has brought forward some remarkable statistics to prove that whilst pulmonary phthisis is steadily decreasing, tabes mesenterica in children under one year—*not, be it noted, in older children*—is decidedly increasing, and from these figures he draws some important deductions.

It seems, however, desirable first to inquire what the term "tabes mesenterica" really means when applied to children under one year. Broadly, and yet strictly, it may be taken, I imagine, to signify one or more of the following conditions: tuberculous peritonitis, tuberculous enteritis, and caseation of the mesenteric glands. How frequently do these conditions occur in children under one year and to what extent are they diagnosable? 1. Tuberculous peritonitis, I take it all authorities are agreed, is rare in children under two years—almost unknown in those under one year. I have only met with one example—viz., in a child aged one year and nine months—in a series of 300 consecutive post-mortem examinations upon children under two years which I have myself performed at the Victoria Hospital, Chelsea, and in the post-mortem records of the hospital for the last ten years I can only find one other case and that was in a patient of exactly the same age. 2. Tuberculous ulceration of the bowel and caseation of the mesenteric glands may best be considered together, for when either one is at all advanced the other is rarely absent. That they occur with considerable frequency in young children is undoubted. In the series of 300 necropsies just referred to tuberculous mischief was present in the intestines or mesenteric glands, usually in both, in 36 cases (18 under one year and 18 between one and two years).

At first this comparatively large number seems to coincide with the recorded frequency of tabes mesenterica in the national death statistics, but on further examining the clinical and pathological records of these cases it was found that in nearly all the abdominal lesion was merely a part, usually quite a subsidiary part, of a more general tuberculosis. 12 were ordinary examples of tuberculous meningitis and certainly could never be regarded as cases of tabes mesenterica; in most of the others pulmonary mischief was predominant during life and was found post mortem to be far more extensive and advanced than the abdominal lesions; in fact, in only 3 of the cases (1 being the case of tuberculous peritonitis already mentioned and the other 2 being by no means typical) was there any probability of tabes mesenterica being diagnosed with reasonable confidence during life. Moreover, on what is a diagnosis of caseation of the mesenteric glands to be based? If they can be felt well and good, but probably everyone will admit that they are rarely palpable, whilst if the diagnosis be made from such symptoms as wasting, fever, &c., the possibilities of error are enormous. But it may be said that at any rate tuberculous enteritis gives rise to more definite and characteristic symptoms. What symptoms?—pain, diarrhœa, wasting, a big abdomen, fever. Are there not plenty of other causes for these in infants? What justification have we, without confirmatory evidence elsewhere, for assuming them to have a tuberculous origin, especially if the records of pathological experience give no support to such a view? In children over two years of age the matter is of course different.

I fully agree therefore with the statement in Ashby and Wright's "Diseases of Children" that "mesenteric disease is much more frequently diagnosed than discovered post mortem"; but, if so, what is the real nature of the thousands of fatal cases of so-called tabes mesenterica in young children? Simply, I believe, marasmus the result of chronic gastro-intestinal catarrh. An infant is brought up by hand; its food disagrees, it gets gastro-intestinal catarrh which leads to distension of the abdomen, griping pains, chronic and very intractable diarrhœa, and occasional vomiting. Of course the child wastes steadily; it has perhaps irregular pyrexia (though I suspect that the temperature is not as a rule very systematically taken in these cases). The mother suggests that the child has "consumptive bowels," the medical practitioner agrees; it is the simplest way out of the difficulty and saves the necessity of taking much further trouble in treatment, and after death he writes "tabes mesenterica" on the certificate; it is an attractively impressive term and no doubt conveys much consolation to the afflicted parents. These cases are to be seen, of course, by the hundred at any children's hospital, but they are not tuberculous—the necropsy proves that. I have notes of nearly 100 post-mortem examinations on such cases, all children under two years of age In only one was any abdominal tuberculous lesion present and that was merely early caseation in the mesenteric glands and one nodule in the intestine, yet in very many "tabes mesenterica" might have been diagnosed with much confidence but for the wholesome corrective of pathological experience. We need to know definitely how we stand in this matter and I hope to elicit expressions of opinion from other hospitals for children. If tabes mesenterica be common in infants by all means let us deal with it, but if, as I firmly believe, it is comparatively rare, let us try to diffuse a knowledge of the fact throughout the profession and so put an end to much erroneous certification.

Do not let me be misunderstood. I fully believe that milk may and frequently does convey tuberculosis and that if the supply were pure the mortality from genuine tuberculous diseases would be materially diminished, though I maintain that so-called tabes mesenterica in infants would be almost unaffected, except in so far as any improvement in the milk-supply would diminish the dangers of gastro-intestinal catarrh. But if we persuaded the public to adopt the precautions with regard to cows and to milk which we recommend and afterwards found that the chief disease we had attributed to infective milk was as rampant as ever, assuredly a very harmful reaction would follow; the public would look to us for an explanation, and what satisfactory one could we give compatible with our professional self-respect?

Another point arises in Sir R. Thorne's lectures. He states that tuberculous meningitis has increased and that this disease, like tabes mesenterica, is essentially due to the reception of the tuberculous infection into the alimentary tract. This statement raises two questions. First, has tuberculous meningitis really increased, or is the increase more apparent than real and due to increased correctness in diagnosis? for many cases now properly described as tuberculous meningitis would no doubt in former years have been included under "hydrocephalus," "convulsions," &c. Secondly, is it, as a matter of fact, usually due to infection through the alimentary canal? It is, of course, as a rule merely part of a general miliary tuberculosis, and to produce this an infective centre must exist somewhere, if in the abdomen in caseous mesenteric glands or possibly in old tuberculous ulcers of the bowel. This raises questions too wide to be brought within the limits of a letter, and it is the less necessary inasmuch as I have discussed them in a paper read before the Medical Society of London and published in THE LANCET of May 12th, 1894. In that paper I tried to prove on post-mortem evidence that tuberculous disease in children started much more frequently in the thoracic than in the mesenteric glands, and that presumably therefore (though this does not necessarily follow) the infection is derived more frequently from the respiratory than from the alimentary tract. Statistics published by Dr. Colman from the records of the Hospital for Sick Children, Great Ormond-street,[1] coincide closely with mine. I know that Dr. Sims Woodhead, from post-mortem results in Edinburgh, attaches much greater relative importance to the mesenteric glands and it seems very desirable that the whole subject should be further investigated.

So far, however, as Sir R. Thorne's statement about tuberculous meningitis is concerned, I have gone through my notes of 44 necropsies on cases of that disease in children specially examined with a view to determining the primary focus of infection, and in 31 the infective centre was almost certainly in the chest, usually in the bronchial or tracheal glands; in only 2 was it certainly in the abdomen; in 6 it might have been either in the chest or in the abdomen; and in 5 it was in other parts of the body or was not found. In 14 of the cases there was not even any sign of tuberculous mischief in either the mesenteric glands or intestine, whilst in nearly every case there were caseous and softening glands in

[1] Brit. Med Jour., vol. ii. 1893.

Digitized by Google

the thorax. Certainly, so far as they go, these figures do not support the idea that tuberculous meningitis is mainly due to the reception of tuberculous infection into the alimentary tract—unless, indeed, as is possible, the bacilli obtained access through the alimentary canal but without necessarily giving rise to any local lesion either there or in the mesenteric glands.

I am, Sirs, yours faithfully,

Cavendish-place, W., Dec. 6th, 1898. J. WALTER CARR.

THE ANTI-TUBERCLE CRUSADE.

To the Editors of THE LANCET.

SIRS,—In a book written by Gideon Harvey, M.D., about 1660, consumption is described as an endemic and epidemic disease and the following passage gives some idea of the then prevalent belief in its infective nature: "And considering with all its malignity and contagious nature, it may be numbered among the worst Epidemicks or popular diseases, since next to the Plague, Pox, and Leprosie, it yields to none in point of contagion; for it's no rare observation here in England, to see a fresh coloured lusty young man yoake to a consumptive female, and him soon after attending her to the grave. Moreover nothing we find taints sound lungs sooner, than inspiring or drawing in the breath of putrid ulcered consumptive lungs; many having fallen into consumptions, only by smelling the breath or spittle of Consumptives, others by drinking after them; and what is more, by wearing the Cloaths of Consumptives, though two years after they were left off."

With the exception of the last sentence this opinion so nearly accords with the views of to-day that it is difficult to understand why it remained in abeyance for so many years. Of course it was not founded upon a scientific basis and, I suppose, as we became more exact we were unable to accept the clinical facts unless supported by experimental proof. Thanks to the discovery of Koch we are now emerging from the path of error into which we had temporarily strayed and in doing so I think we must admit that we should have been wiser, or at any rate conferred more benefit on mankind, if we had accepted the teachings of our predecessors who, if they had not the advantage of so much scientific knowledge to assist them, evidently possessed considerable clinical acumen and were able to make accurate deductions therefrom. There are, of course, errors in Gideon Harvey's book, but who can say that some of the statements are not in advance of even our boasted knowledge of to-day? As an instance we may take the reference to cancer as infective. Although we are still disinclined to accept it the disease affords us indications which support the view that it is to some extent communicable. The great factor which upsets all our calculations is the individual peculiarity which favours the development of a disease, and it is because we are unable to solve this problem that we must use every means in our power to prevent the products of infection being brought into contact with any member of the community.

A society has been established for this purpose the members of which intend to propagate information which will enable the laity in some measure to assist in the endeavour to control the disease. An eminent member of the profession has delivered a discourse on this subject wherein he chiefly lays stress on the danger of drinking milk and indicates the necessary means of avoiding this danger. He also recommends asses' milk as superior because less likely to be infected with tubercle. In this connexion it is interesting to note that Gideon Harvey had noticed this although he did not know the reason. Writing on the subject he says, "Asses' milk is universally preferred," and he goes on to give directions as to the diet of the ass—a matter which may or may not be of importance. In speaking of the treatment he is also very strong on the question of fresh air and change of air and also advocates change of food. "Neither it's only the change of air that proves so soveraing to Consumptives, but the change of Bread, Beer, Flesh, Company, and other circumstances do very much conduce thereunto." It is necessary to consider this question not only in the treatment, but also as a preventive, and although we are often met with the remark, "Oh! if I listen to you it is not safe to eat anything," it is nevertheless our duty to warn the public and teach them how to avoid disease. All authorities seem to be agreed upon the importance of safeguarding our food supplies, but although most elaborate precautions are taken for this purpose one of the prime sources of danger, at any rate as regards tubercle, is ignored.

Take, for instance, the inspection of bakehouses which is carried out in a fairly thorough fashion. The drains, the structure, &c., and all the appliances must be kept in a sanitary condition—i.e., in such a condition that germs will not be likely to flourish about them—but no notice is taken of the attendants, one or more of whom may be and often is suffering from phthisis, his body full of dangerous germs which are constantly fouling the atmosphere; the expectoration finds a rapid drying-ground and a temperature favourable to the life of bacilli, while the crevices in the already baked bread and other foodstuffs form a ready nidus for their reception and propagation. In these days, when hardly any bread is made in the homes, it is a question whether there is not even more danger from bread than from milk, for it is well known that phthisis is a prevalent disease amongst bakers. True, I have not got the scientific proof of my assertion and I might examine many loaves before I found tubercle bacilli. Many samples of milk might be examined with a negative result, but given the presence of tubercle bacilli in a bakehouse—and I suppose few would deny their existence there if the baker was suffering from phthisis—I do not think it is necessary to resort to scientific experiment to prove the danger. When phthisical subjects are being solemnly enjoined to carry receptacles for their sputum in order to avoid the danger of infecting the atmosphere of our towns surely there is no difficulty in realising the far greater risks in a bakehouse. Again, if it is necessary to rigidly supervise the sanitary conditions in order to ensure an atmosphere where food may be produced without fear of its being infected, surely it is approaching well nigh the ridiculous to permit an infected individual to be there present, to prepare the food, to handle it when prepared, to foul it with his exhalations and to deposit the products of his disease in and about the building. In the flour mill too phthisical workmen will often be found, and though the process of baking will perhaps sterilise the flour it is used for many other culinary purposes which may not.

Although I give the first place to bread my remarks apply to all consumable stores. If it is necessary to inspect the slaughter-house and to examine the meat, why except the butcher? Cooking should kill tubercle bacilli, but so should it destroy the eggs of the tapeworm, and yet in spite of this we annually extract many yards of this disagreeable denizen from the intestines which no doubt have been introduced in the same way as much of the tuberculous mischief finds entrance to our bodies. If ham, cheese, and butter require examination, why allow them to be retailed by a phthisical shopman? In like manner I might pass in review all articles of diet. I might even enter the sacred precincts of the domestic household and question the bodily condition of the cook and those who carry the food to the ultimate consumers. The position of safeguarding the food-supply and ignoring the condition of those who handle it seems to me a very untenable one and demands the immediate attention of those who are constituted the guardians of the public health. Will it take us as long to insist on the remedy as it has taken us to accept the fact of the infectious nature of tuberculous disease? Without expressing any disbelief in the views of Sir Richard Thorne and yourselves as expressed in your leading article of Dec. 3rd I venture to assert that the question I now raise is a point in favour of including phthisis among the dangerous infectious diseases which are compulsorily notifiable to sanitary authorities. I do not say that it proves the necessity of such an inclusion, but it does make for the necessity of investing all sanitary authorities with the power of inspecting not only the premises and the food, but also the bodies of those persons who are occupied with the food. This inspection should be no superficial formality but a rigid and thorough examination carried out at regular intervals.

In the meantime at the expense of being called an alarmist I would commend to the serious consideration of all thoughtful men the question of their food-supply. Do not be satisfied with boiling your milk; try to secure servants free from tuberculous disease and be particularly careful about your bread.

I am, Sirs, yours faithfully,

Kidderminster, Dec. 5th, 1898. J. LIONEL STRETTON.

THE COLLEGE OF PRECEPTORS.

To the Editors of THE LANCET.

SIRS,—I trust you will permit me to point out a serious inaccuracy in the first paragraph of the report of the Education Committee of the General Medical Council as printed in THE LANCET of Dec. 3rd (p. 1519), to which paragraph much importance appears to be attached in your first leading article. In the paragraph it is stated that—

During the years 1892-98 returns have been made to the Council on behalf of the Examining Boards for the Navy, Army, and Indian Medical Services, respecting those candidates for appointments who showed deficiency in general education. In the case of 10 of these candidates the particulars given were insufficient to enable the preliminary examination to be traced; in the case 29 the examination passed by the candidate was one of those at present recognised by the Council. In no less than 14 instances the examination by which the candidate had gained admission to the Student's Register was that of the College of Preceptors, while the remaining 15 candidates had qualified by one or other of *nine* of the recognised examinations. There were, in addition, 16 candidates who had qualified for registration by means of the examinations of the Society of Apothecaries or the Royal College of Surgeons in Ireland, but the examinations have now for some years been discontinued.

It thus appears that of all the examinations now on the Council's list the College of Preceptors' is that which most frequently gives rise to animadversion on the part of the examining boards and that the college contributes to the returns of comparative failure almost as many instances as all the other educational bodies together. It is also worthy of note that the returns report no single instance of deficiency in general education on the part of a student registered by means of a university local examination.

It cannot be doubted that the above statement, coming as it does in the forefront of the report, must have had great weight in determining the decision of the Council, and it might reasonably have been expected that scrupulous care would be taken to test its accuracy before making it public. A careful examination, however, of the published minutes of the General Medical Council, in which all such cases are recorded, shows the real figures to be as stated in the following table:—

Preliminary examining body.	Navy.	Army.	Indian.
College of Preceptors	1	1	—
Royal University of Ireland...	—	1	—
Royal College of Surgeons in Ireland	—	3	—
Royal Colleges of Physicians and Surgeons in Ireland	1	—	—
Apothecaries' Society	1	—	—
Apothecaries' Society and Edinburgh University	—	1	—
Aberdeen University	1	—	—
Trinity College, Dublin...	1	1	—
University of Edinburgh and Colleges of Physicians and Surgeons, Edinburgh	—	1	—
Not traced	8	2	7
Totals	13	10	7

It will be seen that the total number of cases is 30 and that of these only 2 are those of candidates who are reported to have obtained their qualifying certificates from the College of Preceptors. Both these cases, it may be added, are cases of deficiency in *spelling*, which is not quite the same thing as "general education."

I am, Sirs, yours faithfully,

H. W. EVE,
Dean of the College of Preceptors.

Bloomsbury-square, London, W.C., Dec. 7th, 1898.

"DIPHTHERIA ANTITOXIN IN PRIVATE PRACTICE."

To the Editors of THE LANCET.

SIRS,—You have done great public service in publishing several recent communications on the use of, and the neglect in using, the antitoxin of diphtheria. The admirably short and practical article by Mr. E. C. Bousfield in THE LANCET of Dec. 10th following upon those of Dr. Cobbett and Dr. Goodall can scarcely fail to correct the difference between the success of cases treated in private and in hospitals—a difference which used to be in favour of the private practitioner but which is now in favour of the Metropolitan Asylums Board hospitals. The correction, as Mr. Bousfield's experience shows, would be very quick, very obvious, and very satisfactory to private practitioners. My own experience, though very limited compared with his—for until of late years diphtheria used to be almost unknown in Highbury—is quite to the same effect. My object in writing is to say so and to encourge private practitioners in the use of the antitoxin. One great reason for the non-use of the antitoxin is the want of arrangements for getting it easily when wanted. The sanitary authorities of this parish have been most exemplary of late in supplying means for expediting and facilitating the diagnosis of typhoid fever and diphtheria. They would do great further good by having on hand a supply of antitoxin, on sale, but to be readily got by practitioners on any day and at any time of night or day.

It is sad to think what an amount of preventable mortality takes place in London and the country for want of such ready means of getting antitoxin. In regard to large sections of the population it is a question of money, and this is clearly a case where the remedy should be available at the public expense where the patient is too poor to command it.

One thing in this connexion must be gratifying to you—that in your editorial capacity you have repeatedly pointed out the grievous defect which has now been shown by your correspondents in a light which must throw a great responsibility alike on sanitary authorities and private practitioners. As private practitioners we are all anxious to show the advantage of private as compared with hospital treatment. Here is a case where we have an exceptional chance of doing so. I am, Sirs, yours faithtully,

Highbury-place, N., Dec. 13th, 1898. JAMES GREY GLOVER.

To the Editors of THE LANCET.

SIRS,—It is with great pleasure that I have seen that the question of the early administration of antitoxic serum in cases of diphtheria has been again referred to in THE LANCET.

As an assistant medical officer in one of the Metropolitan Asylums Board hospitals I can confirm Dr. Goodall's statement that it is quite unusual for a patient to have been injected before admission and this in spite of the now well-known fact that early treatment is all important. Doubtless in many cases the patient's friends neglect to call in a medical man until the symptoms are severe and of some duration, hence, however prompt the notification and removal, such patients come into hospital late. If, however, we are to believe the statements of some patients' friends I am afraid that sometimes the fault lies with the medical attendant in not recognising either the nature or the gravity of the case. It is most disappointing and disheartening to residents in hospital to admit cases which they recognise at first sight to be almost certain to die and to find out that the patients have been under medical treatment for some days before being notified and that they have not been treated with serum. It seems to me that it is the absolute duty of a medical man to inject every child whom he *suspects* may be suffering from diphtheria as soon as possible after he sees such child. If this were the common instead of the, alas, uncommon practice I firmly believe that scores of lives would be saved every year in London. I hope that there is no difficulty in the way of obtaining the remedy and a suitable syringe seems to me to be a necessary part of a medical man's outfit in this city where the disease is so prevalent. The value of the remedy is now so universally recognised that it is no longer a question to be doubted.

My object in writing is to express a hope that THE LANCET will strongly take up the question of educating public opinion as to the necessity of seeking immediate medical advice in cases of "sore throat" in children and also to point out to medical men that it is in their hands often whether recovery or death shall ensue not only in cases remaining under their care but also in those admitted to a hospital. I am convinced that several of our patients would have recovered if they had been injected even only twenty-four hours before admission and many more if they had been injected two days before.

I am, Sirs, yours faithfully,

Dec. 12th, 1898. AN ASSISTANT MEDICAL OFFICER.

"THE 'OPEN-AIR' TREATMENT OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—Dr. Lionel Beale is apparently under a serious misapprehension in regard to the practice of the open-air treatment. He seems to imagine that an "open shed" constitutes the whole provision made for the consumptive's residence, and that in this the patient has to sleep, dress, and take his meals. So far from this being the case it is well known to most practitioners that the treatment is usually conducted in well-appointed houses, that the bed-rooms are carefully warmed while the patients dress and undress, and that meals are taken in comfortable dining-rooms. The daytime only is spent in the sheds which are merely adjuncts to the main building and afford shelter from wind and rain while the patient lies out of doors. Under these circumstances I will not say that the patient's mind does not to some extent reflect the state of the skies, but as a matter of experience I think that the sense of well-being engendered by the open-air life together with a certain feeling of expansiveness that these patients enjoy have a greater effect upon their spirits.

I am, Sirs, yours faithfully,

Norwich, Dec. 13th, 1898. F. W. BURTON-FANNING.

THE FEES OF PUBLIC VACCINATORS IN THE WYCOMBE UNION.

To the Editors of THE LANCET.

SIRS,—The committee appointed by the meeting of public vaccinators of this union met the Finance Committee of the board of guardians to-day and agreed to the scale of fees subjoined. It shows in nearly every case an increase on that proposed by the board, the fixed amount being agreed upon owing to the difficulty in computing mileage:—

	Scale proposed.	Scale agreed to.
(*a*)	For the whole Union 1*s.* 0*d.*	2*s.* 0*d.*
(*b*)	District 1 5*s.* 0*d.* Urban.	5*s.* 0*d.*
	,, 2 6*s.* 0*d.* Rural.	7*s.* 6*d.*
	,, 3 6*s.* 0*d.* ,,	7*s.* 6*d.*
	,, 4 5*s.* 6*d.* Urban and rural.	6*s.* 0*d.*
	,, 5 5*s.* 6*d.* Chiefly rural.	7*s.* 6*d.*
	,, 6 6*s.* 0*d.* Urban and rural.	6*s.* 6*d.*
	,, 7 5*s.* 6*d.* ,, ,,	6*s.* 6*d.*
	,, 8 5*s.* 6*d.* ,, ,,	5*s.* 6*d.*
	,, 10 and 11 6*s.* 0*d.* Rural.	7*s.* 6*d.*
	,, 12 6*s.* 0*d.* ,,	6*s.* 0*d.*
(*c*)	2*s.* 6*d.*	2*s.* 6*d.**
	Union and schools 2*s.* 6*d.*	5*s.* 0*d.*

* With fresh arrangement if stational vaccination should be resorted to.

This was accepted by the board.

I am, Sirs, yours faithfully,

HUMPHRY J. WHEELER.

High Wycombe, Bucks, Dec. 13th, 1898.

THE PRESENTATION TO MR. E. M. OWENS.

To the Editors of THE LANCET.

SIRS,—Every surgeon in the mercantile marine will peruse with pleasure the note in THE LANCET telling of the presentation to Mr. E. M. Owens of the s.s. *Nineveh* and will congratulate that gentleman, while at the same time they will compliment the captain and owners on the recognition of the "single-handed" ability of their surgeon. It is rarely such an appreciation is given of work well done at sea, hence the more reason it should be emphasised. The time has gone by when a surgeoncy at sea was regarded as the "refugium peccatorum." Nor does one read in the papers "that this ship carries a doctor and a cow." Nowadays the position of medical officer on board one of the great liners is very eagerly sought after, while to get a return trip to some favourite port is so coveted that men of the best reputations are willing to pay a fee of two guineas and do the work for nothing, much to the detriment of many young men who require to be paid for the service. I hold that no man in a professional capacity has more responsibility on his shoulders than the surgeon of the modern steamer, whether it be an Atlantic liner with sometimes 2000 people to look after or one of the numerous vessels going to South America, Africa, or Australia; and by the way, these ships do not come as a rule under the surveillance of the medical department of the Board of Trade. Medical men at sea cannot send round the corner for advice or assistance; whether it be "a clinker in the eye" or a "strangulated hernia" they must be ready and able to operate at a moment's notice; therefore the surgeon at sea must be self-contained, self-controlled, and capable of coping with any emergency. There are no V.C.'s for the surgeons of the Mercantile Marine, although I know men who have done deeds worthy even of that high prize. It would be interesting if Mr. Owens would publish his case in THE LANCET, as, apart from the interest of the paper, many a man who through carelessness or modesty has neglected to register his experience would now perhaps contribute something of the medical, surgical, or hygienic conditions of sea life which I have no doubt would be full of interest and instruction.

I am, Sirs, yours faithfully,

Henrietta-street, W., Dec. 12th, 1898. R. A. CALDWELL.

A FERTILE ALTHOUGH UNSUSPECTED SOURCE OF BACILLARY INFECTION.

To the Editors of THE LANCET.

SIRS,—From cases of pulmonary tuberculosis which have come under my own observation I am of opinion that in many instances diseased cage-birds, such as canaries, linnets, &c., communicate tuberculosis to a serious extent amongst human beings. As about 400,000 canaries are reputed to be sold every year in the United Kingdom the distribution of tubercle by this bird alone, when disease attacks it, must be considerable. In a recent work by Friedberger and Fröhner[1] it is stated that tuberculosis is one of the most common diseases of birds. I hope in a short time to send you evidence from cases which I have investigated in support of my assertion.

I am, Sirs, your obedient servant,

Montreux, Switzerland. TUCKER WISE.

"A CASE OF DEATH FROM DIABETES MELLITUS IN WHICH THAT DISEASE GAVE NO PREMONITORY SYMPTOMS."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Pavy's letter in THE LANCET of Dec. 3rd in reference to the case published under the above title on Nov. 26th I should like to make one or two remarks.

On reference to the case in question it will be seen that I never for one moment lost sight of the fact that the attack might have been one of an apoplectic seizure but was driven to the diagnosis I adopted from the following succinct reasons:—1. There were none of those signs present which one would have expected to have found if the attack had been one of apoplexy. (*a*) The arteries were in excellent condition for a woman of her age. There was no sign of atheroma in the peripheral arteries and no sign or history of syphilis to account for an arterial degeneration of that description. The pulse, too, was free from tension. (*b*) The heart was normal in every respect. There was no hypertrophy, no murmurs of any description, and no accentuation of second sound. 2. The presence in the urine of a somewhat large amount of glucose (16 grammes per 1000), which I ventured to think was greater than would have been the case if it had merely been a temporary glycosuria accompanying an apoplectic stroke. 3. Of the "air-hunger" symptom I will only say that this, in conjunction with the afore-mentioned signs, assisted me, but only in an indirect manner, in confirming the diagnosis I arrived at.

I do not see that there should be any more "disquietude" in connexion with a case of this kind than there is with an apoplectic seizure itself. In fact, I think that the latter—which, as is well known, may occur with little or no premonitory symptoms—is of a more alarming nature than a case of diabetes mellitus which ends in a similar manner; for surely if such a case be diagnosed early its

Digitized by Google

conditions might be ameliorated by prescribed diet, &c., and thus banish or postpone for an indefinite time a coma which otherwise might prove shortly inevitable.

I am, Sirs, yours faithfully,

Dec. 6th, 1898. T. WILSON PARRY.

"BILATERAL ACUTE LABYRINTHITIS."

To the Editors of THE LANCET.

SIRS,—In your last issue you describe the case related by Dr. Percy Webster in the *Intercolonial Medical Journal* as a very rare one. As a *primary* acute labyrinthitis it certainly would be so, but after reading the notes one cannot help thinking that the case was one of cerebro-spinal meningitis with *secondary* implication of the labyrinth, a by no means rare complication of the disease and one which aural surgeons fully recognise as being a cause of deaf-mutism in children.—I am, Sirs, yours faithfully,

Harley-street, W., Dec. 12th, 1898. ARTHUR H. CHEATLE.

THE INFLUENCE OF THE NERVOUS SYSTEM IN HEART DISEASE.

To the Editors of THE LANCET.

SIRS,—In his Purvis Oration on Some Points in the Treatment of the Chronic Forms of Heart Disease due to Rheumatism, published in THE LANCET of Dec. 10th, Dr. Sansom described a case of cardiac dilatation in which remarkable benefit followed the use of galvanism in the course of the vagus, and suggested that "special treatment of the nervous system in rheumatic diseases of the heart is in many cases of very high importance." In this connexion the researches of Balint, published in the *Deutsche Medicinische Wochenschrift*, Jan. 6th and 13th, 1898, appear to me to be worthy of notice. By Rosenbach's method and also by a hooked sound Balint produced aortic incompetence in dogs, cats, and rabbits. In certain cases two of the aortic cusps were torn off. The animals were kept under observation till death. Hypertrophy of the heart was the invariable result, but there was no failure of compensation even when two of the valve cusps had been removed. The maximum period of observation was 293 days. Balint then injected phosphorus oil after ablation of the valves as in the previous experiments. Fatty degeneration of the heart muscle was thus produced, but there was no failure of compensation. This, of course, bears out clinical experience. The fatty degeneration of the myocardium in pernicious anæmia, &c., is not attended with the phenomena of broken compensation. In his next experiments Balint cut one or both vagi after the removal of the valves. In dogs and cats loss of compensation occurred, even when one vagus was divided long after the destruction of the valves. In rabbits no such effect was produced. No change was found in the myocardium in these cases. Balint concludes that the nervous mechanism of the heart plays a very important part in the disturbance of compensation. These experiments have so great a bearing upon Dr. Sansom's clinical observations that further work appears to be demanded upon the same lines.

I am, Sirs, faithfully,

JAMES H. SEQUEIRA, M.D., M.R.C.P. Lond.,
Medical Registrar, London Hospital; Physician to the North-Eastern Hospital for Children.

West-street, Finsbury-circus, E.C.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND "TRADE."

To the Editors of THE LANCET.

SIRS,—What is truth? said jesting Pilate. What is trade? might be seriously and anxiously asked by many a medical man, especially by those familiar with by-law 176 of the Royal College of Physicians of London, which ordains that "no Fellow or Member of the College shall be engaged in trade, or dispense medicines, or make any engagement with a chemist or any other person for the supply of medicines, or practise medicine or surgery in partnership, by deed or otherwise; or be party to the transfer of patients or of the goodwill of a Practice to or from himself for a pecuniary consideration."

If, for example, the President or any of the Censors or anyone else were to establish a grocer's shop, write his name over the front and devote the intervals of time unoccupied by his public and private professional duties to weighing out and selling tea and sugar over the counter, there would be no need to ask the question in such a case, for he would be indubitably engaged in trade. But if, instead of selling tea and sugar (or anything else) in a shop of which he is the sole proprietor, he becomes a shareholder in Lipton's or any other public limited company, is he not equally engaged in trade? He might perhaps purchase and hold shares in one of the numerous "stores" which sell, among other promiscuous things, "patent" or quack medicines, and thereby derive profit from this pernicious class of goods. He may, moreover, be not merely a shareholder, but a director of the company, and thus take an active and responsible part in its management. If so, is he not still further engaged and immersed in trade?

Everyone knows (through the advertisements which are so liberally distributed) that several Fellows of the College sit on the board of the Clerical, Medical, and General Life Assurance Company. Others are to be found on the managing committee of a Coöperative Wine Society, Limited, which, if not an association trading for direct and immediate dividends, at least trades judiciously so as to obtain the best results and strives to avoid pecuniary loss. I do not find fault with such gentlemen for being thus connected with honourable and useful commercial undertakings and I do not think such employment to be "derogatory to the position of a physician" necessarily. The possession of business capabilities is a credit to their owner even if he be a statesman and the talent should not be hidden away in a napkin and buried. But is its exercise consistent with the College by-law and is the by-law itself unexceptionably reasonable? Or perhaps—

"That in a captain's but a choleric word
Which in a soldier is flat blasphemy."

I am, Sirs, your faithfully,

Dec. 6th, 1898. PUZZLED

"AN ACADEMIC GOWN FOR THE MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND."

To the Editors of THE LANCET.

SIRS,—Please oblige by the following correction. In the second paragraph and third line of my letter the word "sash" should have been "cap."

I am, Sirs, yours faithfully,

THE SECONDER OF THE RESOLUTION FOR THE
Dec. 12th, 1898. MEMBERS' ACADEMIC GOWN.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Spread of Plague.—Anticipations of further Outbreaks.—The Disturbances in Mysore.—Nursing under Difficulties.—The New Agreement with the English Plague Medical Officers.

THE gradual spread of plague in the southern portions of the Bombay Presidency, in the Mysore territory, and in the Madras Presidency still continues. Other parts are at present free with the exception of a few cases at Karachi, in the Punjab, in Cutch, and in the city of Bombay. Plague has broken out in the Central Provinces at a place called Hinganghaut, about 40 miles from Nagpore. The so-called necessary precautionary measures towards staying the spread of the disease are reported to have been instituted. These consist apparently of segregation camps and hospitals with disinfection on an extensive scale. The already condemned quarantine is once more applied. Notwithstanding that the weather conditions are just now admittedly favourable nothing is heard of clearing out the people *en masse*—the only remedy which has hitherto proved of any material value. If this were done the annoyance of all other measures might be avoided. With reference to the outbreak at Rahon in the Punjab it appears on further inquiry that the disease has long been concealed by the inhabitants from fear of the regulations adopted for dealing with plague in the country around. The connivance of the native police at this concealment has been proved and there are probably many more cases than those which have been brought to light.

Digitized by Google

A report has been spread that plague had broken out in Delagoa Bay, but it has not been officially confirmed. Some time ago it was said that certain forms of a bubonic disease had been observed in Uganda, but its identity with plague was never definitely established. Little or nothing has been heard about it since.

There have been serious disturbances at Seringapatam. Thousands of persons with all sorts of improvised arms attacked the police and endeavoured to rescue the prisoners, but very prompt measures seem to have been adopted and 13 rioters were killed and large numbers were wounded.

It is anticipated, apparently, by the plague authorities in Bombay that another recrudescence may occur at no very distant date. For this reason camps are being maintained and the services of the English Plague Sisters are being renewed for a further period. Against the early development of another recrudescence is the fact that Bombay has only just passed through an abortive third outbreak which attained its maximum the first week in October. An interval of quiescence at any rate may first be hoped for. Plague has by no means left the city, but only 33 deaths from it were recorded for the past week.

The Presidency plague mortality for the past week shows a considerable improvement, although in the southern parts it is still raging with severity. In the Satara district there were 370 deaths, in the Belgaum district 915 deaths, in the Dharwar district 1873 deaths, and in the political agency of Kolhapur 466 deaths. The total mortality from plague for the week was 3990, being 868 fewer deaths than during the previous week.

Madras city records only 2 seizures and 2 deaths. In the districts there were 32 seizures and 30 deaths. More medical men have been requisitioned to supplement the medical service in this Presidency.

It is reported that at Bangalore, where the outbreak is very severe, some 35 closed-up and deserted private dwellings, warehouses, and shops were forced open. Dead rats were found in nearly every building. The buildings were subsequently disinfected and ventilated. It is also reported that bullock carts which had been used to convey dead bodies (three and four at a time) to the cemeteries and which had not been disinfected have been used by people fleeing from the town by the ordinary road routes. The military are now being used in Bangalore and are doing excellent work in the congested low caste localities, detecting large numbers of concealed cases every day. As yet no serious opposition has been shown to their employment. They proved of great value in Poona, but in Bombay the people rebelled against their employment.

At a village called Khed in the Poona district it is stated that there has been a severe mortality from plague amongst pigs. Now that the monsoon is over and the weather is favourable evacuation of infected villages is being enforced in many of the outlying districts of the Bombay Presidency.

The following figures are supplied to show the protection afforded by inoculation in the town of Dharwar:—

	Present population.	Total attacks.	Total deaths.
Once inoculated	3074	106	37
Twice inoculated	3557	17	4
Uninoculated	3089	1118	879

Plague has now almost disappeared from this town. To illustrate some of the difficulties of plague nursing in the remote districts may be mentioned the contrivance adopted at one place which was rapidly and severely attacked of utilising old kerosene oil tins for the construction of bed-pans so hard pressed was the staff for medical and nursing conveniences.

Many of the medical men sent out to India from England have been asked to continue their services under a new agreement. Although this offers a slight increase in salary it does not provide for leave, or for carriage allowance, or for exchange compensation. It binds the medical man for service for twelve months, whereas the Government can terminate the service in six months. It makes no provision for payment of money in lieu of a return passage if the medical man does not wish to return home direct. It definitely excludes any private practice and compels all the time to be devoted to plague duties. While admitting that the salary is fairly reasonable the other conditions are very unsatisfactory. The work is very rough and the medical experience is of little value. The time spent in India means "rusting" in other studies.

Nov. 26th.

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1585.)

ANY occurrence tending to delay the application of energetic sanitary reforms in Belfast cannot be considered otherwise than as disastrous, yet it must be confessed that the measures proposed are entirely lacking in comprehensiveness. There is no attempt to face the problem boldly in all its aspects. The fact that the whole of the sanitary services and arrangements of the town are fundamentally wrong has not yet been fully realised. The tendency is therefore towards patchwork remedies and a little tinkering here and there. To begin with there should have been a system of main sewers for both sides of the river instead of bringing the sewage from the south side over to the north side by means of a syphon under the river. On the Antrim side the main collecting sewer could have been prolonged to the deep sea. On the County Down side it should also have been conducted to the sea. This was proposed at the time that the sewers were built but rejected on account of the cost. Now sooner or later the town will be compelled to incur much greater cost, for there is nothing more extravagant than short-sighted economy. The extension of the borough boundaries so that they now include all the surrounding suburbs renders it even more urgent to reconsider the whole drainage scheme. In some of these added districts, such as Ligoniel, the fall is ample, and here notices are being served on householders to connect with the main drainage system. But what is going to be done in the Lower Sydenham and Green Castle districts where the ground is below the level of the high tide? This part is only protected by an embankment and may be flooded at any moment if an accident occurs to this slender barrier. At Lower Sydenham the owners of land are told by the municipality to raise the level of their ground artificially before they begin to build upon it, otherwise it will be impossible to drain their houses. The owners of the property declare, however, that this would so increase the cost of building that the houses could no longer be let at a remunerative rent. But why do people buy land for building which is obviously not suited for that purpose? Such blundering is not a sufficient reason for imposing extra high rents on tenants, or else for allowing them to live in houses which by reason of the unwholesome ground on which they stand will engender disease and shorten life. It is time that the voice of the tenants should be heard—they are the vast majority; and even from the financial point of view it would pay to attend to their interests. Councillor Jaffe pointed this out to me in a very business-like manner. He argued that even among the poorer sections of the community a death might be estimated as involving, in the cost of the funeral, the medical attendance, &c., a clear loss of on an average £10 per person. There is no reason to doubt but that with proper sanitation the death-rate of Belfast might be reduced 4 per 1000 per annum. This would mean the saving in twelve months of something like 1200 lives. This is something to go upon in arguing from the humanitarian point of view and those who now actively resist sanitary reform should be made to understand that they are actively helping to kill more than 1000 of their fellow citizens per annum. But Councillor Jaffe did not discuss this point of view, his mind was, for the time being, wholly concentrated on figures and he urged that 1200 preventable deaths meant a needless loss of £12,000 to the community. For this annual sum at 4 per cent., which was enough to include amortisation, £300,000 could be borrowed. This would go a long way to remedy the sanitary defects of Belfast. But if this were done a much larger saving would be realised than the loss involved by deaths, for a still greater and more expensive amount of sickness would also be prevented. For instance, last year there were 336 deaths from typhoid fever, but there were 3269 cases of this disease notified. What applies to typhoid fever applies also to other diseases. Thus the cases which were not fatal, being so much more numerous, must have occasioned a far greater financial loss than that represented by the deaths alone. If on the latter an

Digitized by Google

economy can be realised that would suffice to defray a loan of £300,000, then an expenditure of £1,000,000 could be covered by the saving to be realised on the prevention of both deaths and sickness. Nor is there anything extravagant in such an anticipation, for the reduction of the Belfast death-rate by 4 per 1000 would still leave Belfast with a death-rate slightly in excess of that of London. But for every 100,000 inhabitants in Belfast there are more than 1,000,000 inhabitants in London. Belfast also is a new town built after the truth of the modern principles of sanitation had been proved and were generally known. Nor should there be as much poverty and overcrowding in Belfast as in London. Then Belfast has the advantage of proximity to the sea, for the broad salt waters of the Lough are within two miles of the town and constitute an arm of the sea. Finally, if Belfast is as pious as it professes there should be less vice and drunkenness than in London. The death-rate should therefore be below and not above that of London.

There are few towns where so much religious fanaticism is displayed as in Belfast and yet the sense of public duty has been constantly obliterated by the desire to make money. For the sake of money the law has been set at defiance and this by the very persons who are entrusted with the duty of applying the law. This is very clearly set forth and chapter and verse are given in what is known as the Harrison Report which I fully analysed last year.[1] The Public Health Act of 1878 stipulates that ashpits shall be properly covered, that there shall be back passages, that houses shall not be built on ground impregnated with fæcal, animal, or vegetable matter, yet these rules in many instances were not applied. The result of such negligence is that typhoid fever is endemic when it does not assume the epidemic form, and Belfast has a much higher death-rate than London, though, with the advantages it possesses, it should have a much lower death-rate. Yet even at this hour and in spite of the clear evidence of undeniable facts the chief transgressors are ever seeking to mask their own shortcomings by accusing others. Thus, for instance, I have met owners of bad property who lay all the blame on the water-supply and on the factory system. It has never been proved that the water-supply was contaminated before it reached the houses, but the pollution of the subsoil and the insanitary condition of the houses, the privies, and the drains have been demonstrated over and over again. Nevertheless, the owners of this insanitary property try to show that if it is not the water then it is the factory system which causes the epidemics. The house-owners object to spend money to put their property in order, but they do think that the manufacturers should pay higher wages. The women workers at Belfast are not organised as in Lancashire, they consequently cannot maintain the Lancashire rate of wages and earn much less. While at work they neglect their children, and the latter go to work too soon as half-timers. The wretched pay which they obtain means that they must live on insufficient food. Also they have contracted the fatal habit of spending a large portion of their slender earnings on tea which they boil for a long time, thus extracting all the injurious properties of the leaf. Tea and bread-and-butter too often constitute the staple food. So clear is it that the workers suffer from insufficient food that some of the better and more generous employers have established soup-kitchens in their manufactories. This is notably the case at the Jenimount Mill where soup is provided for the workpeople at a charge below the cost price. Doubtless there is some truth in the complaints, but two blacks do not make one white. The wages undoubtedly are very low, but there are opportunities of obtaining employment in Belfast not so easily found in most other towns. There are many light trades in which women and girls can earn some money; thus all except the young children are often able to earn something. Though the individual earnings are small the collective incomes of the entire family often amount to a fair sum. Also the large number of workmen employed in the ship-building yards earn much higher wages and yet typhoid fever has been rife in their families as well as among other sections of the community. Undoubtedly the fact that the mother is at work in a mill renders it almost impossible to maintain a healthy and cleanly home. This objection, however, applies to other manufacturing towns where typhoid fever is not so constantly and disastrously prevalent. Of course, it is very difficult to maintain good sanitation in the midst of poverty; but that difficulty is increased to an incalculable extent when the houses inhabited by these poor people are deliberately built on infected soil and are devoid of the most essential necessities for the preservation of health. Then, again, if poverty is so very prevalent in Belfast, how is it that working people from all parts of not only Ireland but even of England crowd to that town in the belief that they will be able to earn better wages? Intemperance, combined with the want of orderly, cleanly, and economical habits is undoubtedly a great factor in the spread of disease; but these predisposing causes are not special to Belfast; they are great evils, but they exist elsewhere. It would be difficult, however, to find elsewhere so complete a disregard of the elementary principles of sanitation as that which has been displayed in the building of workmen's cottages in Belfast.

For many hours each day young children are left alone in these cottages. They play in a back-yard which is badly paved and drained. Close by is a privy and ashpit, it leaks or overflows in the yard, there are pools of stagnant water, and the children's hands and clothes are soon soiled with filth which contains organic material in decomposition. Some of this is carried with the fingers to the mouth. Where there is a little door to empty the ashpit this door is often not securely closed. The children force it open and amuse themselves pulling out some of the soiled contents of the ashpit. There is no one in charge to prevent them indulging in such a dirty and dangerous pastime. This, doubtless, has often been the cause of disease among children; and it may well be said that if better wages were paid there would be no need for thus leaving the children alone. But, on the other hand, if, instead of a filthy, open, leaking privy, there was a properly-constructed water-closet, if the receptacle for household refuse and ash was securely covered and closed, if the yard was efficaciously drained and well paved, these children, though neglected and left to their own devices, would not run so great a risk of contracting some disease. Where the back-yards are paved small tiles are very generally used. These are easily broken; the children can lift them up and soon gain access to the foul earth underneath. Holes and indentures are formed in which dirty water remains stagnant. In a short time the children are left to play all day long on what is little better than a dung-heap. Such yards should be paved with heavy flagstones or in some other way rendered secure against the wear and tear to which they must be exposed. It does not seem, however, as if anything really effective had been attempted. A rule has certainly been enacted to the effect that where pigs are kept in a back-yard the pigsties must be built at a distance of at least 15 ft. from the walls of the house. This is a very small step in the right direction. The keeping of pigs in a town should not be allowed under any conditions. Then the distance of 15 ft. will be but a poor protection if the yard is not properly paved and drained and if the filth from the pigs can soak in the soil or flow towards the walls of the house—a condition of affairs which very generally prevails. Nor is it at all certain that the rule about the distance of 15 ft. is strictly applied. Even dispensary medical officers who act in the capacity of medical officers of health in their districts are, I was assured, not always disposed to testify before a court that a pig constitutes a nuisance. It would be incurring the risk of great unpopularity to enforce sanitary measures against pigs in Ireland, yet this must be done if the Irish wish to live healthy lives in large towns.

(To be continued.)

[1] THE LANCET, Dec. 11th, 1897.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary.

THE poll of the trustees of the Manchester Royal Infirmary asked for by Dr. Renaud on Nov. 21st was announced on Dec. 8th. 1284 voting papers were issued and 779 were returned, 12 being spoiled, with the result that the amendment was carried by a majority of 341. It may be remembered that the resolution was in favour of rebuilding on the present site, while the amendment asked the infirmary board to re-open negotiations with the corporation with a view to the sale of the whole of the infirmary area, necessitating, therefore, the removal of the hospital to another site, but with the

Digitized by Google

proviso that there should be an accident and out-patients' department in the centre of the town. The amendment having now become the substantive resolution will have to be voted on at another meeting of the trustees. If it should be adopted the way will be open for negotiation with the corporation for the sale of the infirmary site. Assuming that these negotiations are successful the corporation can no doubt provide a considerable amount of the purchase money by the sale of the old town-hall in King-street, now used as the free reference library, and of the art gallery, formerly known as the Royal Institution, in Mosley-street. In the opinion of one of the weekly papers the latter would be "an admirable building for the reception of accidents, emergency cases, and a dispensary for out-patients." It would have one qualification, publicity, as it is in one of the best known and most frequented streets in Manchester; but it would therefore command a very high price and the interior of the building would require complete re-arrangement, while it is doubtful if there is sufficient ground space. There would not be much difficulty in finding a suitable and not extravagantly costly site for this central building. As to the position of the infirmary itself there will be much discussion and great differences of opinion. Some members of the staff favour the Stanley Grove site in Oxford-road, not very far from Owens College, and with the Whitworth Park, a picturesque and extensive open space, on the opposite side of the road. A great deal may be said for this site in addition to the fact that it was offered in 1896 by the Whitworth trustees practically as a free gift and it is believed that the offer is still open. If this site is passed over the reasons for doing so ought to be of extreme cogency.

Oldham and the New Vaccination Act.

Even those who most regretted the passing of the new Vaccination Act could have little anticipated the scenes—which might be called farcical if not fraught with evil presage for the future—which have followed that well-intentioned but weak and disastrous measure. Two special sittings of the Oldham justices were held on the evening of Dec. 8th beginning at six o'clock to grant certificates of exemption. Two courts were held to speed on the work, one for women and one for men. Four magistrates were in the men's court and two in that for the women, but they were unable to cope with the crowds that crushed into the corridors and every passage available. They sat from 6 P.M. on the Thursday to 1 A.M. on Friday morning, but before that time the applicants lost patience, "expressed their feelings in vehement language"—which phrase used with reference to the Oldhamese tongue means something exceedingly strong—"turned on water-taps in the neighbourhood and generally turned the town-hall into a pandemonium." The six unhappy magistrates are said to have signed at least 7000 certificates in the seven hours, having no doubt weighed carefully each objection to make sure that it was "conscientious." The total number granted up to that time was 17,000 and since then further sittings have been held to provide pabulum for the next visitation of small-pox. It is said that there are 40,000 anti-vaccinationists in the borough, "and as printed forms of the certificates can be obtained up and down the borough further scenes may be expected." The ignorance of these naturally quick and, in a narrow way, shrewd and clever people is something extraordinary and their proceedings under the recent Act inclines one to doubt their fitness for this measure of home rule. Somewhat similar scenes are reported from Ashton-under-Lyne, Stalybridge, and other places in the north. "Several hundred exemption certificates were granted at Keighley yesterday." When Nemesis appears will Parliament or the people be held responsible?

Salford Sanatorium.

It is proposed to enlarge the Salford Sanatorium by the addition of two convalescent pavilions for scarlet fever and typhoid fever patients, with accommodation for nurses and a resident medical officer. At present two large pavilions are always occupied, leaving only one for other diseases, and convalescent and acute cases have to be mixed up in one ward, while lately there has been increased difficulty through a small epidemic of typhus fever. Application is to be made to the Local Government Board for sanction to borrow £19,550, the estimated cost of the additions.

Proposed Sanatorium for Phthisical Patients.

A deputation from the Manchester and Salford Sanitary Association was received by the Health Committee of the Salford Corporation on Dec. 8th. Its object was to suggest to the corporation the desirableness of providing a sanatorium for phthisical patients. Dr. Leech and Dr. Williamson put before the committee cogent arguments in favour of their suggestion and the rector of St. Stephen's, Salford, stated from his knowledge of the people in the neighbourhood of the town-hall that he could confirm all that Dr. Leech had said as to the existence of conditions favourable to the spread of phthisis. The deputation was received with sympathy but was reminded of various difficulties (including cost) in dealing with the matter and the chairman invited the Sanitary Association to provide lecturers on the subject of the prevention of phthisis and said they would find audiences. Dr. Leech promptly agreed to this and also to a suggestion that the association should organise a conference of all corporate, Poor-law, and hospital authorities in the district to discuss the subject. The association intends to interview various other authorities.

Dec. 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Reception at the Royal College of Surgeons of Edinburgh.

THE reception given by the President of the College and Mrs. Chiene, reference to which was made in THE LANCET of Dec. 10th, passed off with great *éclat* and was largely attended by the members of the profession in the city and its neighbourhood and their wives.

Edinburgh University Total Abstinence Society.

This society is to be addressed on Thursday, Dec. 15th, by Dr. G. Sims Woodhead of London, who takes such a prominent place in the temperance movement.

The Christmas Vacation in Edinburgh.

The medical classes will rise for the Christmas vacation on Wednesday, Dec. 21st, and will resume work on Wednesday, Jan. 4th, 1899.

The Scottish Cremation Society.

The annual meeting of this society was held in Glasgow on Dec. 7th, the chair being taken by Sir Chas. Cameron, Bart., M.P. In moving the adoption of the report the chairman alluded to the relatively slow progress of the movement but considered that this was to be expected in the very nature of things. The number of cremations during the last year was 10, but at the Woking crematorium similar slow progress had been experienced at first. He detailed the safeguards insisted upon by the directors with a view to guard against cremation in any case of foul play and contended that these regulations were a far more complete protection to society than the present rules governing the registration of deaths which latter he described as scandalous. The meeting was also addressed by Professor Sir Henry Littlejohn and by Dr. Ebenezer Duncan.

Sanitary Matters in Paisley.

A further contribution to the conflict between the Paisley local authorities and their medical officer of health is furnished by a report from Professor R. M. Buchanan of Anderson's College Medical School who has made an elaborate bacteriological examination of samples of the domestic water-supply collected during the recent outbreak of enteric fever. This examination failed to detect the typhoid bacillus, but the report submits reasons why this negative result is not to be considered conclusive, and moreover, affirms that as the samples contained pseudo-typhoid and coliform bacilli in large numbers there is abundant evidence of sewage pollution.

The Greenock Fever Hospital.

The local health authorities have received from Mr. R. Murray, inspector under the Local Government Board, who some time ago paid a surprise visit to the hospital, an intimation that the Board is of opinion that the accommodation in the fever hospital is insufficient for the needs of the district. The health committee has therefore to face the prospect of building a new hospital.

Committee on Reformatories for Inebriates.

Among the witnesses recently examined by this committee

Digitized by Google

appointed by the Secretary for Scotland are Dr. J. F. Sutherland, deputy commissioner in lunacy for Scotland, and Dr. John Wyllie, consulting physician to the Edinburgh Royal Infirmary.

Dec. 14th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Richmond (Dublin) Lunatic Asylum.

AT the meeting of the governors of the Richmond District Lunatic Asylum held on Dec. 9th the medical superintendent (Mr. Conolly Norman) reported that a patient in one of the female wards was recently found to be suffering from fracture of one of her ribs and that no explanation of the injury could be elicited from the nurses in charge of the patient. He strongly urged that they should be all dismissed.

Cork-street Fever Hospital and House of Recovery, Dublin.

At the meeting of the Managing Committee of this institution on Dec. 8th the registrar reported that scarlet fever cases showed a marked decline in numbers but an increase in the severity of the type of disease prevailing. A few cases of typhus fever were admitted, one from outside and the others from inside the municipal boundary. Enteric fever cases maintained the usual average. Several cases of pneumonia which proved rapidly fatal were admitted during the latter part of the month. Several cases of measles were admitted from institutions and a few patients suffering from diphtheria. The last-named disease has never been severely prevalent in Ireland.

Death of Dr. James Hamilton of Bray, co. Wicklow.

Dr. James Hamilton whose death took place at his residence in Bray on Dec. 9th was a graduate of the University of Dublin having obtained the degree of M.B. in 1872. Dr. Hamilton was a comparatively young man in considerable private practice and his untimely death is much deplored in the district.

The Water-supply of Belfast.

Two very important letters have been published in the Belfast papers in reference to the chemical analysis of the water supplied to the city. One is from Dr. Letts, Professor of Chemistry in Queen's College, and states that he has repeatedly expressed the view that the water is not of good quality, basing his opinion on the results of frequent examinations which show that the "albuminoid ammonia" has often risen above 0·02—"the oxygen absorbed" amounts to from 0·3 to 0·4 and the "organic nitrogen" exceeds 0·02—and on the fact that the sources of the water were liable to dangerous pollution. In conclusion he advises that "the less the town supply is used by its inhabitants for drinking purposes the safer it will be for them." The second letter is from the demonstrator in chemistry in Queen's College, Mr. R. F. Blake, F.I.C., F.C.S., who gives an analysis made on Dec. 3rd of water drawn from a tap connected with the main in the chemical laboratory of Queen's College. He states that his figures condemn the water as utterly unfit for drinking purposes owing to its pollution by an excessive amount of organic matter of vegetable origin. He found 0·0185 part of albuminoid ammonia per 100,000. Having given the results of his own analysis he proceeds to criticise those of Messrs. Barklie and Hodges who were asked by the Water Commissioners to examine and report. He shows first that their results differ considerably, as, for instance, the one finding 0·026 part of organic nitrogen per 100,000, while the other only obtains traces of organic ammonia; while there is every reason to believe that 0·026 part of organic nitrogen would yield 0·019 part of organic ammonia which is not a trace but more than sufficient in itself to condemn the water. Mr. Barklie says that his chemical examination of the water was satisfactory and that the water-supply of Belfast is at present purer than at any other period. But Mr. Blake asks, Is a water with 0·026 part of organic nitrogen satisfactory? Dr. Percy Frankland in 1892 found this amount in an analysis of Belfast water and he suggested filtration, but there is the same amount in the "filtered" water analysed by Mr. Barklie. The filtration at Stoneyford, Mr. Blake therefore concludes, has done no good. Again, Mr. Blake asks, Why has Mr. Barklie omitted to determine the albuminoid ammonia? Dr. Percy Frankland did so in 1892 and found 0·019 part per 100,000, corresponding to 0·026 organic nitrogen. How then, asks Mr. Blake, can Mr. Barklie state that the Belfast water is purer than at any other period when according to Dr. Percy Frankland we know that 0·026 part of organic nitrogen corresponds to 0·019 part of albuminoid ammonia (as far as this water is concerned) and Mr. Barklie himself found in 1887 as little as 0·014 part per 100,000? Mr. Hodges from his figures says he does not consider the water polluted with animal matter, though it does contain organic matters of vegetable origin somewhat in excess of the quantity found in a previous examination. Mr. Hodges says in his analysis that there are only traces of albuminoid ammonia which means that the water is practically free from organic matter of vegetable origin; but Mr. Blake rejoins that this is not consistent with the report or with the fact that the water was said to be of a greenish-yellow colour due probably to the peaty matter it contained. Further, the water is said to contain as much as 0·004 part of free ammonia per 100,000. Mr. Blake says he knows of no case nor has he seen mentioned in any text-book an example of an "upland surface" water of a greenish-yellow colour yielding so much free ammonia with only traces of albuminoid ammonia. Mr. Hodges's figures give for the "ammonia" from the Woodburn supply only traces, which Mr. Blake says indicates that the water is practically organically pure and of the very first class. Such waters are, however, not usually yellowish-green in colour. I append the analyses of Messrs. Barklie, Hodges, and Blake in parts per 100,000 in a table.

Refuse Disposal and Sewage Purification.

At the Belfast Natural History and Philosophical Society a paper was read on this subject by Mr. W. Chambers, C.E., in which he dealt broadly with those methods which would be serviceable to a city like Belfast situated on a tidal estuary of the sea. An interesting discussion followed and among other matters a communication was read from Dr. Letts, Professor of Chemistry, Queen's College, Belfast, in which he said there were three alternative methods for the disposal of the Belfast sewage: (1) irrigation; (2) the construction of a main sewer to some spot on Belfast Lough where the sewage would be swept out to sea by the turn of the tide; and (3) chemical treatment. Of these three the conditions for the first are unsuitable, the cost of the second would be too great, so that the third alone was really practicable.

Dispensary Medical Officers and the County Councils.

The question as to whether dispensary medical officers are disqualified by virtue of their office from being elected and acting as county councillors has been referred to the Local Government Board who in reply stated "that the Order

Digitized by Google

in Council dealing with the matter has not yet been made, but the Board consider that serious inconvenience might be caused to the sick poor if the dispensary medical officer undertook public duties of this nature outside his district."

Dec. 14th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Use of Oxygenated Water in Surgery.

AT the meeting of the Academy of Medicine which was held on Dec. 5th sundry speakers gave the results of researches which they had made upon the use of oxygenated water in surgery. M. Lucas Championnière said that during the space of one year he had made clinical trial of this agent and had found that oxygenated water was an antiseptic of remarkable power, and of special value in cases of suppuration or septic infection. Solutions of 10 or 12 parts by volume seemed to act best and were very superior to solutions of perchloride of mercury. A solution of oxygen is not only capable of checking putrefaction but will also prevent its occurrence. In vaginal hysterectomy a preliminary douching of the canal with this solution gives better results than any other antiseptic fluid. In cases of septic infection after abortion washing out the uterus with oxygenated water is just as satisfactory a method of treatment as curettage. In addition to the properties already mentioned oxygenated water is a hæmostatic. On the other side M. Charpentier argued that the liquid would not keep and moreover was an admirable culture medium for the streptococcus. M. Ferrand also spoke against it, saying that peroxide of hydrogen was not only an irritant but actually a caustic. M. Monod said that in his opinion nothing was better than a carbolic spray and M. Labbé agreed with him. M. Laborde spoke in his turn in defence of the oxygen solution, saying that it was absolutely harmless and could be used as an intravenous injection. In reply M. Lucas Championnière, while quite allowing that the solution in question was very unstable, argued that it could be obtained from the manufacturers in a state of great purity and was certainly far superior to phenol.

Thyro-iodine in Delayed Union of Fractures.

The Society of Surgery held a meeting on Nov. 30th, when M. Quénu read a paper upon the Use of Thyro-iodine in the Treatment of Fractures where Union is Delayed. M. Quénu brought forward two cases. The first was that of a young woman, aged twenty-four years, who owing to a fall sustained a compound fracture of the lower third of the femur. After reduction of the fragment suppuration occurred and a false joint formed. Three months after the accident—that is to say, in July, 1898—M. Quénu saw the patient who was then suffering from a suppurating false joint. Thyro-iodine was administered in capsules and by the fifth day the patient could walk aided by the support of a silicate splint. At present consolidation is practically complete. In this case, then, the administration of thyro-iodine was followed by a very marked growth of bone. In the second case consolidation took place satisfactorily, and although the patient had no thyroid gland, yet she absorbed the thyro-iodine with ease. The patient was a woman who was suffering from post operative myœdema following a thyroidectomy. Ordinary thyroid treatment relieved this condition but two months afterwards the patient fractured her leg. The fracture united in the ordinary space of time but she was treated with thyro-iodine during the whole time of healing of the fracture. M. Reclus brought forward a case occurring in one of his patients who had sustained a fracture of the thigh. Consolidation was very slow and in addition an enormous callus formed. Not knowing very well what to do for this condition it occurred to M. Reclus to give thyro-iodine. The effect of this was immediate, the callus disappeared with remarkable rapidity, and firm union was obtained. M. Reclus confessed, however, that in two or three other cases in which he had employed the same treatment the drug had no influence—a fact which he was quite unable to explain.

Statistics of Medical Students.

M. Brouardel, the Dean of the Faculty of Medicine, laid before the Council of the Academy at its last sitting some interesting figures dealing with the students and the subjects of study at the Faculty of Medicine. The number of students enrolled is 4495; the Faculty includes 351 male foreign students, of whom 16 are Swiss, 15 Germans, 60 Roumanians, 67 Ottomans, and 66 Russsans; there are also 87 female foreign students, of whom 83 are Russians. The 4495 students are studying the following subjects: for the degree of M.D., old regulations, 3261; for the degree of M.D., new regulations, 877; for the *officiat de santé*, 146; as midwives, 94; and as surgeon dentists, 117.

Obituary.

The death of Professor Laboulbene at the age of seventy-three years is announced. He had held the chair of Historical Medicine at the Faculty of Paris since April, 1879; was physician to the hospitals and a member of the Academy of Medicine. His clinical knowledge was unrivalled and he was also an expert naturalist, so much so that he would have held a chair of Entomology or Parasitology with as much distinction as he did that of History of Medicine.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

German Practitioners Abroad.

THE joint committees of the Berlin Practitioners' Associations (Geschäftsausschuss der ärztlichen Standes-Vereine) have asked the Imperial Chancellor that the German consuls may be instructed to supply the said committees with information as to places abroad where there may be openings for German practitioners. The Berlin Practitioners' Associations several years ago formed a medical agency of their own, conducted *honoris causâ* by members of the associations. This agency undertakes to procure locum-tenents for practitioners, both in Berlin and in the country, and to inform young medical men of available vacancies. As the medical profession is overcrowded and as the candidates are always more numerous than the places to be filled the task of this agency has become more and more difficult. The managers have therefore decided to provide facilities for German medical men who may desire to practise in foreign countries. In the petition addressed to the Imperial Chancellor it is requested that the consuls should supply particulars as to the conditions under which German medical men are allowed to practise in the countries in question, as to the capital required, and as to the time which is likely to elapse before practice becomes remunerative.

Improper Treatment by an Unqualified Practitioner.

At a recent meeting of the Berlin Medical Society Dr. Kutner showed a patient who had suffered considerably as the result of treatment by an unqualified person. The man having observed a "blister" on his penis, consulted an individual named Falbe and was informed that the complaint would last about ten weeks. Falbe then poured a corrosive fluid upon the penis, covered it with cotton-wool, and instructed the patient to apply bandages moistened with the same fluid, a bottle of which was given to him. The penis and the skin of the scrotum and the lower part of the abdomen became exceedingly swollen and the patient felt very ill, but was informed by the quack on several occasions that he was on the way to recovery. At last he consulted Dr. Kutner who found that the skin of the penis, the scrotum, and the abdomen was burnt and partly gangrenous, that the "blister" was a chancre, and that an indolent swelling of the inguinal glands and a syphilitic exanthem had developed. Dr. Kutner remarked that if medical men would more frequently bring forward instances in which actual harm had resulted from treatment by unqualified persons the effect might probably be that even those medical men who were opposed to anti-quackery legislation would become convinced of the necessity for repressing unqualified practice.

Diarrhœa in Strangulated Hernia.

A case of strangulated hernia without obstruction of the bowels is reported by Dr. Baron in the *Deutsche Medicinische Wochenschrift*. A woman, forty-three years of age, suddenly complained of severe pain in the right inguinal region, together with gastralgia, copious vomiting, and diarrhœa. A medical man consulted by the patient believed the symptoms to be due to acute gastro-intestinal catarrh and administered

Digitized by Google

ice by the mouth and morphia. When Dr. Baron saw the woman late in the evening she was vomiting bilious matter which had no fæcal odour; there were also profuse diarrhœa and a swelling in the right inguinal region of the size of a walnut. The skin over the swelling was normal, and there was no inflammation of the surrounding tissue. After injection of morphia the pain and the diarrhœa stopped. On the following morning an operation was performed and although there had been no symptoms of occlusion the above-mentioned swelling proved to be a strangulated hernia. After reduction of the intestine the pain and the other symptoms at once disappeared and the patient very soon recovered. Diarrhœa in strangulated hernia is a very rare occurrence; Malgaigne termed it "choléra herniaire" and believed that the prognosis was fatal. Dr. Baron is of opinion that in his case an acute enteritis preceded the strangulation and that the diarrhœal stools came from the portion of the intestine beyond the strangulated tract.

Affections of the Bladder in Workers with Aniline.

At the German Surgical Congress, Professor Rehn of Frankfort described some cases of growths of the bladder occurring in workmen employed in chemical factories, especially those where fuchsin is made. He expressed his opinion that the vapours developed in the manufacture of fuchsin produced an irritation of the uropoëtic system which finally led to the formation of malignant growths. Dr. Leichtenstern, chief physician to the Cologne General Hospital, writing in the *Deutsche Medicinische Wochenschrift*, states that long ago he also observed urinary troubles in these workmen, especially in the form of strangury and hæmaturia. He refers to similar observations made by Dr. Grandhomme of Hoechst, Dr. Stark of Cologne, and Dr. Bachfeld. Aniline and toluidin are especially liable to produce irritation of the bladder. The patients in question were employed in the so-called reduction department of the factory where nitro-benzol is converted into aniline, amidotoluol converted into toluidin, and fuchsin produced from those two compounds. In this department, therefore, the workmen run great risks and prophylactic measures should be taken. Free ventilation is essential in order that they may not be exposed to the influence of concentrated vapours of the above substances, they should be instructed to give immediate notice to the medical officers whenever any urinary troubles occur, and men suffering from a disease of the uropoëtic system ought not to be employed in aniline works. Dr. Leichtenstern in conclusion described 2 cases of tumours of the bladder lately observed by him in workmen from a well-known Rhenish chemical factory. The first patient was a man, thirty-one years of age, suffering from symptoms of chronic aniline poisoning—yellow-green colour of the hair and nails together with anæmia. He had also for several weeks complained of anorexia and strangury. By rectal palpation a globular and very painful tumour was recognised in the bladder. The bladder itself was so small that only 70 c.c. (2½ oz.) of fluid could be injected by irrigation. The daily quantity of urine was from 500 c.c. to 750 c.c. (17 fl. oz. to 27 fl. oz.); it was of a dark-green colour and contained a small quantity of blood. Casts were never present and the reaction was acid. In course of time other tumours formed in the bladder and could be felt on both sides of the symphysis, whilst the capacity of the bladder decreased so much that it would hold only 40 c.c. (1½ oz.) of fluid. The treatment consisted of hot poulticing, hot baths, opium suppositories, and subcutaneous injections of morphia, the effect of which was that the patient gradually improved, the capacity of the bladder increased, the urine became normal, and the tumours disappeared. After six weeks the man was able to leave the hospital with only a slight degree of anorexia and strangury. From this rapid recovery it was evident that the growths were not malignant but that they were due to acute submucous proliferating cystitis. The second patient unfortunately died. He was fifty-one years of age, had been employed for many years in the factory and went to the hospital with nearly the same symptoms as those in the preceding case, but the tumours were much larger and were perceptible above the symphysis. Cystoscopy was impossible, for the cavity of the bladder was practically obliterated, and the catheter could not make its way amidst the large tumours. Notwithstanding treatment as above described the growths increased and cystotomy was therefore performed. The bladder appeared to be changed into a great mass of growths and was completely removed, the ureters being brought out into the wound. The patient died two days afterwards. The necropsy showed that the tumours were reticular polymorphous sarcomata and had grown through the submucous tissue. The cause of the disease was evidently a chronic irritation of the bladder caused by the vapour of aniline, its pathogenesis being comparable to that of the sarcoma affecting chimney-sweeps and workers with paraffin.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The English-Speaking Practitioner in Italy.

WITH a persistence which will not be thrown away upon the English-speaking part of the profession Dr. Santini in the Chamber of Deputies on Dec. 12th once more interpellated the Government as to whether it intended to take cognisance of what he calls "l'esercizio abusivo sanitario per parte dei stranieri" (the irregular practice of the healing art by non-Italian medical men). He took his stand this time on the "national dignity" which was compromised by the non-recognition of Italian diplomas abroad while foreign diplomas are recognised in Italy. In other words, he wanted to make the possession of an Italian qualification obligatory on the foreign (particularly on the English-speaking) practitioners. The Prime Minister (General Pelloux) reminded him of the circular disseminated some weeks ago among the prefects of the kingdom advising them to take note of such foreign practitioners as courted an Italian *clientèle* and to check such practices wherever found, advising them, moreover, that where such practitioners confined themselves to their compatriots the prefectoral interference was not warranted. Before sitting down His Excellency called Dr. Santini's attention to the fact that there are only 108 foreign medical men practising in Italy, of whom, I may add, the English-speaking contingent may be reckoned by units rather than by tens. Admiral Canevaro (Minister of Marine) asked Dr. Santini if he was aware that the Italian practitioners in foreign countries were more numerous than the foreign practitioners in Italy. So it seems that the reciprocity Dr. Santini desiderates already exists and is of so one-sided a character that it is distinctly to the advantage of his compatriots. Dr. Santini in truth seems to have been as far from "scoring" on this as on any previous occasion of the kind.

The Spread of Pestis Bubonica.

The Italian Government, in view of disquieting information from the Madras Presidency and from the island of Madagascar, has, by an ordinance bearing date Dec. 4th, put in force against all vessels sailing to Italy from those parts the regulations embodied in the law on maritime sanitation of May 8th and July 15th, 1897.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Inoculation for "Cattle Tick Fever."

DR. TIDSWELL, the assistant medical officer to the Government of New South Wales, has for the last three months been investigating the effects of protective inoculation of cattle against the cattle tick fever. He has just furnished the Minister of Agriculture with a preliminary report in which he gives a minute description of the disease and the results of his experiments. He observes that these are defective in point of numbers and the time given to the investigation has been too short for the settlement of many of the problems to be elucidated, but sufficient has been done to warrant the following conclusions being accepted as a closely approximate indication of what may be expected from protective inoculation: (1) the inoculation will protect cattle against the serious effects of "cattle tick fever"; (2) provided the animal whose blood is to be used be properly selected the inoculation will not seriously interfere with the milk yield of dairy cows; and (3) in certain cases the inoculation will produce an unhealthy condition which may last for a few months

Digitized by Google

at least and during which the meat will be of an inferior quality. He adds: "The experiments have shown that protective inoculation has its defects as well as its advantages; it is well for those who may practice it to know the exact conditions and be prepared for some disappointments. At the worst estimate it is better than the natural tick fever and it is the best known means of minimising the disastrous effects of the latter disease. What is required is some method of securing immunity which does not involve infection."

Legislation for Inebriates.

On Oct. 13th Mr. Creed moved the second reading of the Inebriates Bill in the Legislative Council of New South Wales. Eleven years ago a committee had reported as to the necessity for legislation of the kind proposed and further experience only accentuated that necessity and the Comptroller-General of Prisons had pressed upon the Government the necessity of treating habitual drunkards as victims of disease and not as ordinary offenders against law. He thought provisions had been made in the Bill to guard against abuse. The first clause authorised a judge of the supreme court or district court, the master in lunacy, or any stipendiary or police magistrate on the application of the inebriate or any person authorised in writing in that behalf by an inebriate, while sober, to make an order placing the inebriate under the care and control of some person or persons, in the house of the inebriate or of a friend, or in a public or private hospital, or in some gaol or receiving-house, for any period not exceeding twenty-eight days, or in some hospital for the insane or licensed inebriate institution for such period not exceeding twelve months, as might be mentioned in the order. The inebriate might also be placed for a period not exceeding twelve months under the care or charge of an attendant or attendants to be named in the order. As to the orders the Bill provided that they might be applied for by the husband, wife, parent, brother, sister, son, or daughter of full age, or partner in business of an inebriate, or an officer of police of or above the rank of a sub-inspector, acting on the request of a duly qualified medical practitioner in professional attendance on the inebriate, or on the request of the relative of an inebriate or at the instance of a justice of the peace. The clause also allowed the inebriate if mentally fit an opportunity of being heard in objection to the order. The second and third clauses provided that the judge or magistrate might make an order as to the property and treatment of the inebriate. The next clause provided that the order should authorise the attendant to prevent the supply of intoxicants to an inebriate and provision was also made that the inebriate should not leave the colony during the existence of the order unless permitted to do so by some variation or amendment of the order. There were provisions in the Bill which to a certain extent related to the property of an inebriate and the question of supplying liquor to inebriates. Clause 9 provided that the Governor might license institutions for inebriates and make regulations and that provision would, he thought, be less likely to lead to oppression than if the regulations were embodied in the Bill.

The Milk-supply of Melbourne.

At the last meeting of the Melbourne Medical Association Mr. Millard Johnson, Ph.L., one of the lecturers at the Veterinary College, and formerly an inspector of milk at San Francisco, gave a very interesting lecture, illustrated by limelight views and experiments, on the chemistry and handling of milk. He gave a detailed account of the many processes adopted in America to secure purity of milk and contrasted them with the laxity and culpable carelessness which characterised the production, handling, and distribution of milk in Melbourne and its suburbs. It was shown that under present circumstances it was extremely difficult to prevent decomposition of milk in Melbourne and that these difficulties were much intensified by the restrictions imposed by the Factories Act upon the distribution of milk prohibiting the delivery of milk on two afternoons in the week. An animated discussion followed and it was unanimously decided that the medical societies should take immediate steps to try to alter the existing state of affairs. In consequence delegates from the various societies met and drafted a letter on the subject to the public press and also arranged for a deputation to the Chief Secretary.

The Board of Health and Tuberculosis in Victoria.

The President of the Board of Public Health in Victoria, Dr. D. A. Gresswell, has prepared a circular on the subject of the prevalence of tuberculosis in the colony and its prevention. In the ten years from 1888 to 1897 19,137 persons have died from tuberculosis in Victoria. It is recommended that milk be not taken from milkmen who cannot show a certificate from a veterinary practitioner that the dairy herd is free from disease and from a medical practitioner that the dairying operations are properly conducted. Meat must not be taken from a butcher who cannot give satisfactory evidence that the meat is wholesome and that in slaughtering and dressing scrupulous cleanliness has been observed. No house or room which has been occupied by a tuberculous patient should be taken unless satisfactory evidence be given that it has been thoroughly disinfected. Tuberculosis amongst cattle must be eradicated—a matter which has been shown to be practicable.

The Meat Bill, Victoria.

Three years ago a conference of delegates from the metropolitan municipalities was held to consider the necessity of improving the conditions of the meat-supply of the colony. The chairman of the Board of Public Health submitted a draft of a Bill which served as a basis for discussion. After several conferences a measure has been finally drafted and is now coming before Parliament. The main object aimed at is to secure that stock of all kinds intended for sale as food shall, as far as possible, be slaughtered under proper supervision. The Bill proposes that after the expiration of six months no person shall slaughter or dress carcasses except at a public abattoir or a duly-registered private abattoir. The municipal councils are to appoint meat inspectors who must prove their competence to the satisfaction of the Board of Health. To secure independence these inspectors are to be removable only by the Governor in Council. The inspector is to have power to enter abattoirs at any time and is enjoined to examine all animals intended to be slaughtered and all carcasses after slaughter. Further clauses prohibit the sale of meat unless branded by the inspector as fit for consumption.

The Battle of the Clubs.

In Launceston, Tasmania, seven of the medical men engaged in lodge practice have signed a circular sent to the various friendly societies in that city refusing to continue their attendance unless some reform is made with regard to fees and a wage limit for members. The friendly societies in retaliation threaten to import two medical men to do all the lodge practice at a definite salary and without the right of private practice. The friendly societies in Hobart tried this system some years ago, but it was a failure.

Presentations to the Matron of the Sydney Hospital.

Miss Gould, prior to her resignation of the position of matron of the Sydney Hospital, received a number of presentations. The honorary medical staff gave a piece of plate and the resident staff an afternoon tea-service. The nursing staff presented a travelling-bag and other articles and the executive staff a clock. All the spokesmen for the various departments referred in the highest terms to Miss Gould's services and the harmonious relations existing throughout the hospital. In acknowledging the gifts Miss Gould referred to the fact that the present nursing staff, including her successor, consisted entirely of colonial women trained at the hospital.

Appointments.

At the Prince Alfred Hospital, Sydney, Mr. F. A. Bennet, M.A., M.D., C.M. Aberd., has been appointed honorary physician for diseases of the skin; Mr. G. T. Hankins, M.R.C.S. Eng., honorary surgeon for diseases of the ear, throat, and nose; Mr. Cecil Purser, B.A., M.B., Ch.B., honorary physician; and Mr. E. M. Pain, medical superintendent. At the Melbourne University the council has made the following appointments of examiners for the year 1898-99 in the Medical School: Anatomy, Mr. G. A. Syme, M.B., M.S., F.R.C.S.; Materia Medica, Mr. P. B. Bennie, M.A., M.D.; Therapeutics, Mr. D. A. Gresswell, M.A., M.D. Oxon.; Medicine, Mr. John Williams, M.D. Edin.; Surgery, Mr. Charles Ryan, M.B., Ch.M. Edin.; Obstetrics, Mr. Rothwell Adam, M.B., Ch.M. Edin.; Forensic Medicine, Mr. C. H. Mollison, M.B., B.S.; Pathology, Mr. T. Cherry, M.D., M.S. For the M.D. examinations: Physiology of the Nervous System, Mr. H. Maudsley, M.D., M.R.C.P. Lond.; Mental Pathology, Mr. J. Y. Fishbourne, M.B. Dub., and Mr. J. V. McCreery, L.R.C.S. Irel.

Nov. 2nd.

Obituary.

SIR WILLIAM JENNER, BART., M.D., F.R.C.P. LOND., F.R.S., &c.

EX-PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; LATE PHYSICIAN-IN-ORDINARY TO HER MAJESTY THE QUEEN AND H.R.H. THE PRINCE OF WALES; CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

WE regret to announce the death of Sir William Jenner which occurred on Dec. 11th, at Greenwood, Bishop's Waltham, Hampshire, a country seat which he had occupied for many years. In him the English medical profession has lost one of its brightest ornaments and foremost representatives, one who had the good fortune to attain to the highest degree of eminence both as a scientific man and a practitioner, and who has now passed away in the fulness of age and universally esteemed. Her Majesty's appreciation of his services to the Royal Family is expressed in the *Court Circular* of Dec. 12th in the following terms:—"The Queen received yesterday with much regret the news of the death of Sir William Jenner who had been Her Majesty's physician for upwards of thirty years and who only retired from the Queen's service in 1893 owing to failing health. He was not only a most able physician but a true and devoted friend of Her Majesty's who deeply mourns his loss."

SIR WILLIAM JENNER, BART., M.D., F.R.C.P. LOND., F.R.S.

William Jenner was born at Chatham in the year 1815, where his father, Mr. John Jenner, resided at the time, although his usual home was at St. Margaret's, Rochester. Of Jenner's early life we know but little, but it seems probable that he received his schooling at the old dockyard town, whither in 1816 Charles Dickens, then a weakly child of four years, had lately come with his parents from Portsmouth. Dickens is described as having loved to watch the games of other boys in which sports his puny physique prohibited his taking part, and it is not too vain an imagining to picture him envying the activity and prowess of the sturdy lad, William Jenner. Jenner's further education was pursued at the University of London (now University College), then in its infancy, his natural bent towards science as a calling there showing itself, and at the age of sixteen years he became apprenticed to an apothecary who conducted a general practice in Marylebone. Having become qualified as a licentiate of the Society of Apothecaries in 1837 he immediately started practice on his own account in Marylebone and with some success. His work was the miscellaneous labour of a middle-class London general practice, but his habits being studious and his energy and ambition well-nigh unlimited it was not long before he aspired to a wider field of effort. For some two years he had been surgeon-accoucheur to the Royal Maternity Charity, when in 1844 he graduated as Doctor of Medicine at the University of London and relinquished general practice. For the next four years he devoted his attention chiefly to the study of pathology at University College where Sir Robert Carswell was lecturing, and in 1848 began, as a Member, his long and distinguished connexion with the Royal College of Physicians of London. At the same time he received the appointment of professorship of Pathological Anatomy at University College and was elected assistant physician to University College Hospital. His active connexion with both these bodies was continued until within a few years of his death, when a dangerous illness caused him to retire from his labours to enjoy a well-earned period of repose.

His connexion with the Royal College of Physicians, commencing, as has been said above, by his becoming a Member in 1848, was as notable as it was long. In 1852 he was elected a Fellow and in the same year he had the honour of delivering the Goulstonian Lectures before the College. In 1881 he was elected to the distinguished position of President, which office he held for seven years—the longest period during which it had been occupied by any physician since the days of Dr. John Ayrton Paris, who presided for thirteen years—from 1844 until 1857. On Sir William Jenner's retirement in 1888 his active part in the management of the affairs of the College ceased, although his influence has since that date been often manifested. As a President he perhaps distinguished himself more than in any of the other numerous honourable capacities in which it was his lot to figure. He worthily upheld the dignity and traditions of the chair occupied by Linacre and Harvey and, with a combination of modesty and thorough commonsense which were ever his notable characteristics, he directed the conduct of the great body of which he was the head during times when the medical profession was undergoing many changes and was decidedly in an unrestful condition.

The Hospital for Sick Children was established in 1852 in Great Ormond-street and Jenner was appointed as its first physician. This appointment he held for ten years, during the greater part of which time Russell Reynolds was his junior colleague. Here it was that Dr. Jenner acquired that intimate knowledge of the pathology and treatment of diphtheria for which his name will long be famous, a subject with regard to which his published works are still reckoned masterpieces of clinical research.

His connexion with the London Fever Hospital began in 1853 when he was elected assistant-physician, and continued until his appointment as Physician-Extraordinary to the Queen in 1861. His appointment at the Fever Hospital accorded well with his other work at Great Ormond-street and at University College Hospital, and although the duties and responsibilities of these three active positions would have been little short of overwhelming to a man of less vigorous determination, Jenner contrived not only to do his share of the work with apparent ease, but at the same time was not forgetful of his social duties.

His "full" physicianship of University College Hospital was announced in 1854, so that between that time and 1861 his days must indeed have been more than sufficiently

Digitized by Google

occupied by official duties, putting aside the considerable private practice which his success had brought him. At University College Hospital in the "fifties"—an institution and period with which the name of William Jenner will always be preeminently associated—among his colleagues were Dr. Walshe, Dr. Russell Reynolds, Dr. Garrod, Mr. Erichsen, Mr. Quain, and Mr. Henry Thompson. Of these, four subsequently received titular distinction.

As physician to University College Hospital and as Professor of the Principles and Practice of Medicine at University College he earned from all who had the privilege of being either his patients or pupils, a regard amounting even to reverence. His style of lecturing was essentially logical, without embellishment, so that in his teachings all that he said was worth hearing not only as a pleasure but as a really valuable help to students in acquiring a knowledge of their profession—a virtue not too often to be found in lectures which are unfortunately so commonly relegated to the category of "necessary functions," dissertations to be listened to or not according to the mood of the hearer for the sole purpose of "getting signed up." Jenner's lectures were certainly not of this latter kind. They commanded the attention of the listeners by the lucid and interesting manner in which their component facts were presented. He was essentially a lecturer who dealt with facts and with facts verified by his own diverse experience. He was in all matters concerning his art an agnostic in the true sense of the word, if we may use an expression so liable to misconstruction—that is, he never asserted anything as a fact until he in his own ripe experience had proved it to be true or had gathered from an absolutely trustworthy source that it was capable of entire verification. His straightforward manner of presenting his ideas in an accurate—nay, almost tabular—sequence can be well compared to the statistical method of his old friend and colleague Dr. Walter Hayle Walshe, to whose friendship and advice many of the great leaders of our profession have owed so much. A veritable galaxy of brilliant men at this period—an era indeed in the history of the science of medicine—formed the staff of University College Hospital—Sharpey, Walshe, Parkes, Jenner, Russell Reynolds, and Garrod, and on the surgical side Richard Quain, Erichsen, Marshall, and Henry Thompson were doing their best work. To the friendship of, and to association with, these men, though several of them were considerably his juniors, Sir William Jenner owed much, not only in the matter of technical assistance, but of brotherly sympathy, for it can safely be said that no man who has ever had the privilege of personal association with Sir William Jenner can fail to regard with affectionate reverence not only his professional greatness but his private and personal worth.

It must be nearly thirty years since Sir William Jenner ceased to take an active part in clinical teaching, so that even his latest pupils are now past middle age, whilst many of the earlier ones have preceded their master to the grave. But to those who do survive the news of his death will recall to their minds his unique personality and the impressive lessons which he imparted to them. Many a maxim which he uttered by the bedside has been treasured by his hearers and has stood them in good stead in times of difficulty. For nothing seemed to escape his observation; and that no sign was too trivial, no detail too slight, to be discarded by the real physician was the gist of his teaching to his assistants. It was an education in itself to be Jenner's house-physician or clinical clerk, for he demanded precision and exactitude and did not hesitate to severely criticise the style and substance of the notes as they were read out to him on his rounds. Nothing slipshod or slovenly was possible in Jenner's wards. It was scarcely possible, however, to please him absolutely and he seemed to instinctively pounce upon the trifle which had been neglected. His remarks were often so direct and so matter-of-fact that in the circumstances under which they were made they appeared to be humorous though whether the utterer intended that this should so appear was often doubtful. These criticisms, freely passed upon house physician, clinical clerk, and nurses alike, formed most instructive and valuable teaching to all concerned and when Jenner perceived that his subordinate received them sensibly and good-naturedly the fact would very generally form the foundation of a friendship which might have an educational and professional value scarcely to be over-estimated. He knew how to teach and what to teach, and he spoke with fearless dogmatism and in an emphatic, terse manner which carried conviction. As an illustration of this and also of his prompt sagacity we repeat the following anecdote upon the evidence of a friend of the late physician who was present. One day Jenner was enlarging upon a possible case of typhoid fever and dwelling upon the differential diagnosis between it and other diseases when he mentioned a sign (we forget what) which, he said, "you never get in typhoid." Upon its being suggested that he spoke too peremptorily on the point, he turned on the speaker and asked, "How often have you seen it in the course of your life? Possibly in one per cent. of the whole number of cases treated? Well, sir, if I succeed in making my pupils 99 times right out of 100 I've done very well."

He never neglected the sanitary side of medicine and always taught his pupils that to prevent was of more importance than to cure. In sanitary matters as in medicine he always made for the essentials, and once when a question of ventilation was being discussed and the value of different methods being canvassed Jenner merely listened to the *pros* and *cons* and then, when everybody had finished, contented himself by saying, "If you want to ventilate the place efficiently you must have the holes big enough." This is a fair sample of his methods and it was marvellous to hear him at a society after listening to the last fine-spun notion upon this or that quietly rise and say a few emphatic sentences which put the whole matter in a nutshell. There was nothing foggy in his mind. He never spoke merely for the sake of speaking and after he had spoken there was no mistaking what he meant or what his line of action would be. When he had made up his mind as to the course of action to be pursued he was not to be turned aside. Sometimes he showed himself scarcely amenable to argument and if pressed was not seldom restive but his opposition was always honest, sincere, and straightforward. It can be believed that University College men were thoroughly proud of their great master. Every medical student of the College felt something akin to reverent awe in his presence. "We were all proud of him," writes one who from his pupil became his colleague and friend; "nay, we worshipped him, although he may not have known it. The pressure of private practice gradually led to his hospital visits being curtailed in number and duration, whilst the clinical lectures which were so full of instruction and wisdom had to be abandoned, and at last the time came when he ceased to visit the hospital at all. Still opportunities did occur in the Pathological and Clinical Societies during his presidency of these bodies, as well as in other medical gatherings, for us to be again under the master's spell, as in his old familiar aphoristic style he spoke of tubercle or cancer or rickets or typhoid fever to an older generation, it is true, but still to those who sat at his feet. But those occasions were few and far between. The world claimed him, and while he filled so well the presidential chair at the Royal College of Physicians the demands on his time left him no leisure to appear at scientific meetings—a veritable loss to the attendants."

On the death of Dr. Baly in 1861 Dr. Jenner was appointed Physician-Extraordinary to Her Majesty the Queen, and in the following year he was gazetted as Physician-in-Ordinary which honourable position he held until 1893, when his health compelled him to resign. From 1863 he likewise acted in the same capacity to the Prince of Wales, and in 1864 he was elected a Fellow of the Royal Society. He assiduously attended the Prince Consort in his last illness — that sad event which deprived the English people of one who had endeared himself to all. In 1868 Her Majesty conferred on Dr. Jenner the honour of a Baronetcy of the United Kingdom, a distinction which was hailed by the whole profession as an honour to the medical calling as well as a well-deserved reward of conscientious and unremitting labour. A very large number of his friends and pupils met together on June 11th, 1868, to celebrate the honour thus conferred. Dr. Parkes took the chair and the dinner which was served at Willis's rooms was a notable event of the medical year. The honour of a baronetcy had been earned by sheer hard work, untiring energy, unblemished honesty and scientific attainments, and in that it rested on no basis of political expediency or private feeling this tribute to the art of medicine was doubly grateful. Jenner was in the prime of life and in the zenith of his success, so that in the speeches delivered on this happy occasion there was no need for panegyrics on his past work. His life's labour was fresh in the minds of all. His contributions to science were part and parcel of the

Digitized by Google

medical knowledge of the day, and among those who were present at the dinner—probably one of the most important meetings of members of the profession for convivial purposes ever held—were an almost unprecedented number of men who owed their success and position to the teachings of the man in whose honour the entertainment was given. Some 200 friends, colleagues, and pupils sat down, including *alumni* of University College drawn from all parts of the United Kingdom. An illuminated address of congratulation was presented to Sir William Jenner by G. V. Poore, on behalf of the students and the health of the new baronet was proposed in the most fitting terms by Dr. Edmund Parkes, when the enthusiastic admiration of a friend was combined with the dignified periods of an orator. Other toasts were given and replied to by Dr. Sharpey, Mr. Richard Quain, and Mr. Malden.

The Prince of Wales's dangerous illness occurred in 1871 and in 1872 Sir William Jenner, who had been in attendance on His Royal Highness during that long and most anxious period and was in great measure instrumental in bringing about the happy issue, was gazetted as a Knight Companion of the Bath. On May 24th, 1889, on his retirement from active work, Her Majesty promoted him to be a Grand Commander of that distinguished Order.

Towards the end of the year 1888 Sir William Jenner became seriously ill and for several weeks his condition was most critical. On Jan. 5th, 1889, however, THE LANCET had the gratification of announcing that during the past week he had steadily improved and it was hoped that he would soon be able to leave London for the country which he was strong enough to do at the end of the month. Throughout his illness he was attended with the closest assiduity by his attached friend and colleague Dr. Russell Reynolds. His health, however, and his age—he had passed the limit assigned by the Psalmist—three score and ten—as well as the advice of his friends, induced him to take a well-earned rest and no further to tax the powers of a physique reduced by his recent illness. He therefore retired from the active pursuit of his profession. But when his years and failing health confined him to his charming country seat he loved to recall the memories of his early struggles, his daily and arduous labours in the wards and post-mortem rooms of the Fever and Small-pox Hospitals, where he worked with an enthusiasm undaunted by the tax it made on his health and comfort. Twice he was attacked by typhus fever and once narrowly escaped with his life. But he was laying then the foundations of his future fame and the same qualities that made him persevere in his researches then were just those which he afterwards carried into every sphere of his labour.

Sir William Jenner's literary works are more notable by their entire originality of thought and great value to the profession than for their bulk and quantity. The most striking points in the studies and experiences of a long life he has recorded, but he has left in the less permanent form of papers to societies and journals much which will be very acceptable to the profession at large for many years to come. His treatise on Diphtheria was published in 1861 and it presented to the profession many observations and details which had previously not received their due meed of attention. Previously to this his Goulstonian lectures had met with recognition as the result of earnest and careful labour as well as expressions of long and useful experience. The memoirs which will always be pre-eminently associated with his name are, "The Identity or Non-identity of Typhus and Typhoid Fevers," "Diseases Commonly Confounded under the term Continued Fevers," and "Acute Specific Diseases"; of these, the first especially aroused marked interest among the leaders of medical science. His opportunities for observing the line of demarcation between these previously confused maladies were exceptional, and he made use of them in a way that few men could have done, but his writings on this subject evoked no little controversy as to priority of discovery—a question which this is not the place to discuss; it will be sufficient to refer to the obituary of Dr. Alexander Patrick Stewart of the Middlesex Hospital, published in THE LANCET of July 28th, 1883. No detail was too trivial to attract Jenner's attention and no symptom went unnoticed or unrecorded. To Holmes's "System of Surgery," Reynolds's "System of Medicine," and Quain's "Dictionary of Medicine" he contributed articles of the highest importance, which indeed rank among the best sections of those admirable works. In 1893 he republished in one volume his "Lectures and Essays on Fevers and Diphtheria, 1849–1879." This volume contains perhaps the best of Jenner's work. In it are included his essays on Typhus, Typhoid Fever, and Diphtheria, to which reference has already been made, and several other valuable contributions which had previously been printed among the Transactions of the Royal Medical and Chirurgical Society. "Clinical Lectures and Essays on Rickets, Tuberculosis Abdominal Tumours, and Other Subjects," was a considerable volume published in 1895. Included in this volume are the two courses of masterly lectures on Rickets which he delivered at the Hospital for Sick Children in Great Ormond street, and although more than a generation has passed since their delivery they are still full of instruction, for they were the product of a keenly observant mind and are stamped with the individuality of their distinguished and lamented author. With regard to rickets to Sir William Jenner must be accorded the great merit of seeing the truth that this disease is, as he put it, "no more of a disease of the bones than is typhoid fever a disease of the intestines." He established it as one of the four diatheses to which infantile life is prone and at the outset of his lectures clearly contrasted the features of these four—tuberculosis, scrofulosis, rickets, and syphilis. His observations concerning the habits of children in later pages are a veritable masterpiece of word painting.

The last of his communications to our pages was entitled "A Brief Analysis of the Appearances observed in the Bodies of Seventeen Persons 'Burnt to Death'" It was dated from Bishop's Waltham, was upwards of seven columns in length, and appeared in THE LANCET of August 22nd 1891. In it he introduces the reminiscence—naturally of much interest to us—that the Founder of THE LANCET (at that time coroner for West Middlesex) was the means of enabling him "to examine the bodies of three people destroyed in a public-house burnt down in Great Portland street."

Sir William Jenner was honoured with, in addition to the many degrees and titles already mentioned, the degrees of Doctor of Laws of Cambridge University and Edinburgh University, and in 1863 had conferred upon him the honorary degree of Doctor of Civil Law by the University of Oxford. He was also a Commander of the Order of Leopold of Belgium, an honorary member of the Academy of Belgium and Fellow or Member of a very large number of learned societies in many of which he has held office as president and vice-president.

Sir William Jenner was married in 1858 to Adele Lucy daughter of the late Mr. Stephen Adey, of Gloucester-place Portman-square, who survives him.

He is succeeded in the baronetcy by his eldest son Captain Walter Kentish William Jenner, of the 9th Lancers of the four younger sons two are in the army, one is in the Consular service, and one is in his father's profession.

The funeral took place this (Friday) morning.

ERNEST DENMAN MINTER, M.B. LOND., M.R.C.S. ENG. L.R.C.P. EDIN., R.N.

STAFF SURGEON ERNEST DENMAN MINTER, R.N., died at the Royal Naval Hospital, Stonehouse, on Dec. 9th, after a short illness. He was the youngest son of the late Dr. J. M. Minter, inspector-general of hospitals and fleets, honorary physician to the Queen, and surgeon-extraordinary to H.R.H. the Prince of Wales. The deceased received his medical education at Guy's Hosptal, London, and graduated M.B. Lond. in 1884; he also took the qualification of M.R.C.S. Eng. and L.R.C.P. Edin. the same year. Dr. Minter entered the Royal Navy as a surgeon in February 1885, and was promoted to the rank of staff surgeon in February, 1897. He was appointed to the *Rupert*, the port guardship at Gibraltar, in December, 1895, and only quite recently returned to England owing to the state of his health.

ROYAL METEOROLOGICAL SOCIETY. — We are informed by Mr. William Marriott, assistant secretary to the society, that on Jan. 2nd, 1899, the offices of the society will be removed from 22, Great George-street, Westminster to Princes Mansions, 70, Victoria-street, Westminster, S.W. to which address all communications on and after that date should be forwarded.

Medical News.

UNIVERSITY OF CAMBRIDGE.—On Dec. 8th Edward Sydney St. Barbe Sladen, M.B., B.C., of Gonville and Caius College, was admitted to the degree of M.D.; H. Williamson, B.A., of St. John's, and H. B. Roderick, B.A., of Emmanuel, were admitted to the degrees of M.B. and B.C.; and Dr. G. N. Pitt has been appointed an additional examiner in Medicine for the M.B. degree.

FREEMASONRY.—*The Rahere Lodge, No. 2546.*—A meeting of the Rahere Lodge was held at Frascati's Restaurant on Dec. 13th, Bro. T. G. A. Burns, W.M., being in the chair. A vote of condolence with the family of the late Earl of Lathom was passed unanimously, Lord Lathom having been an honorary member of the lodge. Bros. Marshall, Heath, Burrows, and Brewerton were admitted to the third degree; Bros. Coventon, Griffiths, Gay, and Tucker were admitted to the second degree; and Dr. C. H. Roberts was initiated into freemasonry. The deputy master for the time being of the Sancta Maria Lodge, No. 2682, was elected an honorary member of the lodge and 20 guineas were voted from the lodge funds in aid of the Royal Medical Benevolent College at Epsom. The members and their guests afterwards dined together.

LEWISHAM UNION INFIRMARY.—Since the opening of this infirmary in 1894 there have been 768 patients of unsound mind under treatment, and a separate building containing three wards and two padded rooms has been erected for the reception and temporary accommodation of such cases. On the occasion of the opening of this building Dr. F. S. Toogood, the medical superintendent of the infirmary, said that it did not inaugurate any new policy because recent Lunacy Acts have made provision for the temporary care of mental cases by giving a justice of peace or magistrate power to order their detention for a short period in a workhouse or infirmary. As showing the connexion between mental and bodily disorder Dr. Toogood said that an elderly female who was admitted suffering from melancholia with suicidal tendencies was found to have a large abdominal tumour, which he removed, and the patient thereupon made so good a recovery that she returned home sound in mind and body and has remained so. Continuing his address Dr. Toogood said: "I feel a certain amount of modesty in speaking of the medical staff and of the treatment of mental cases. The specialist who confines his attention solely to, and whose horizon is bounded entirely by, lunacy is the very worst man to have the care of mental cases in their early stages. What is wanted is great general experience, both medical, surgical, and mental, and I must firmly insist that the medical officers of large institutions such as this are the very men who pre-eminently possess these qualifications. In addition to this they have but a few mental patients under their care at any one time and so are enabled to thoroughly investigate each case. The magistrates and guardians have power to call in any assistance they may deem requisite. Our attendants are trained nurses, male and female, and I have the utmost confidence in them. Dr. Rayner recently delivered a lecture under the auspices of the Charity Organisation Society in which he advocated the formation of 5 or 6 reception houses in the metropolis, these being designed to replace buildings such as this. A similar proposal has also been formulated by the Asylums Committee of the London County Council. The objections to these schemes are many:—1. The total absence of any reason for the change; the present method works well and there have been no complaints of any kind. 2. The great expense; 1000 beds at least would be needed and even the London County Council would find it difficult to erect five buildings of 200 beds each for less than £250 per bed; that means £250,000 for bricks and mortar besides furniture and a host of officers. 3. The impossibility of the medical officers becoming thoroughly acquainted with the cases when dealing with so large a number in such a limited time. 4. The hardship of dragging the patients' friends half across London to attend magisterial examinations. 5. The stigma of lunacy, for by whatever fancy names the reception houses may be called they will inevitably be lunatic asylums to the general public and a working man or woman branded as a lunatic has little chance of obtaining employment in these days of keen competition. After everything has been said systems must be judged by their results and a method such as ours which absolutely cures over half its cases in a fortnight and which only sends one-third to the dreaded lunatic asylum must, to use a colloquial phrase, 'take a lot of beating.'"

MR. J. J. MACKAY, of 154A, Wandsworth-road, has been arrested for perjury on the order of Mr. A. Braxton Hicks, the alleged offence having been committed at the Battersea coroner's court in the course of giving medical evidence at an inquest. He has been released on bail.

INCREASE OF SALARY.—At the meeting of the Bristol Health Committee held on Dec. 6th it was decided to recommend the Town Council to increase the salary of Dr. D. S. Davies, the medical officer of health, by £50 in 1899, and a further sum of £50 in 1900.

MR. W. G. GRACE.—Under the presidency of the Duke of Beaufort a farewell dinner organised by members of the Clifton Beagles and attended by a representative gathering of gentlemen interested in various branches of sport was given to Mr. W. G. Grace, M.R.C.S. Eng., L.R.C.P. Edin., on the occasion of his departure from Bristol.

SOUTH SHIELDS MEDICAL PRACTITIONERS' ASSOCIATION.—At a meeting of this association held on Dec. 8th a resolution was adopted supporting the memorial signed by 309 registered practitioners and laymen and recently presented by the Corporate and Medical Reform Association, Limited, to the General Medical Council against "illegal certificates of proficiency in departments of medicine, surgery, or midwifery." The resolution also thanks the Direct Representatives on the Council and Sir Christopher Nixon, Dr. Bennett, and Mr. Tichborne for their support in the Council of the motion moved by Mr. Brown and seconded by Mr. Horsley—

That a special committee be appointed to consider and report at the next session of the Council all cases of alleged infringement of the Medical Acts by persons who profess to examine candidates in medicine, surgery, or allied subjects and to grant certificates or diplomas testifying as to proficiency in any branch of medical or surgical science.

Resolutions to the same effect have since been adopted by the East Suburban Medical, Ethical, and Medical Protection Society, Limited, and the Beckenham and Penge Medical Society.

THE VICTORIA HOSPITAL FOR CHILDREN.—By permission of the Duke of Westminster a meeting in support of the scheme for erecting a new building for the Victoria Hospital for Children, Chelsea, was held at Grosvenor House on Dec. 12th. It is estimated that the cost of the new building will be £25,000. It is proposed that there shall be 6 self-contained wards on three floors, each with 16 beds. Ample accommodation for isolation of suspicious and infectious cases is to be provided. The operation and anæsthetic rooms are to be on the level of the first floor and the arrangements in the basement are to include a better dining-room for the nurses and store rooms. The Duke of Westminster occupied the chair and was supported by Princess Louise and the Marquis of Lorne. The Chairman explained that the Victoria Hospital was at present housed in a building which was never intended for a hospital. The new hospital would be devoted exclusively to the reception of suffering children, while the present building would be utilised for the purposes of the staff. Mr. Pickering Pick dwelt on the continually increasing demands upon the hospital and said that thirty-three years ago when the hospital was opened there were 39 in-patients and 5147 out-patients, while last year there were nearly 900 in-patients with the same accommodation as in the first year and over 56,000 out-patients. Canon Fleming, in supporting the appeal, said he hoped that the day was far distant when the voluntary system of hospital support would be superseded by State-aid. The Duke of Westminster said the continued growth of the population in London must give them all great anxiety on the score of hospital accommodation. Whether voluntary effort would be sufficient to cope with their requirements in this respect he did not know but he hoped it would. The Marquis of Lorne desired to join with Canon Fleming in the hope that the day was far distant when their hospitals would be supported out of the rates. If the hospitals were rate-aided they would find that those institutions would be called upon

Digitized by Google

to support very many who ought not properly to be supported in them. This was largely the case in British North America.

THE NEW HOSPITAL AT NEWTON ABBOT, DEVONSHIRE.—The old cottage hospital at Newton Abbot being inadequate the late Mrs. Emmeline Fisher gave the munificent sum of £5000 towards the erection of a new building and to perpetuate the memory of her husband, Mr. Edward Fisher of Abbotsbury. Mrs. Fisher also bequeathed a further sum of £2000. The building which was recently opened stands upon a site which is about a quarter of an acre in extent and is situated on elevated ground. The hospital is about 200 ft. in length and 28 ft. in width exclusive of offices. The administrative block is situated in the centre of the building. On the first floor there are 4 bedrooms, nurses' sitting room, &c., and the attic contains 3 bedrooms. There are verandahs on which patients can sit in fine weather. The west wing has a large ward with twelve beds, 48 ft. by 24 ft., a nurses' room, &c., with a board room and convalescent room. The east wing has similar accommodation with the addition of an operating room, with the medical officers' room adjoining. Within the entrance doorway on the right hand side has been placed a marble slab bearing the following inscription: "In commemoration of the Diamond Jubilee of Her Majesty Victoria, Queen and Empress, and in gratitude for the blessings enjoyed under her reign, the people of Newton Abbot, Highweek, and neighbourhood have endowed this Hospital with £1044, to be called the Queen Victoria Fund." On the left-hand side on a stone slab are the words: "This Hospital was erected by Mrs. Emmeline Fisher in memory of Edward Fisher of Abbotsbury."

PRESENTATIONS TO MEDICAL MEN.—At the Townhall, South Bank, Yorks, on Nov. 17th, Mr. John Steele, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., a well-known medical practitioner in the town, was presented by friends and well-wishers in the neighbourhood with a testimonial consisting of a gold English lever watch and chain.—On Dec. 2nd, at the Bradford Infirmary, Mr. H. C. Major, M.D. Edin., who is retiring from the post of honorary physician at that institution, was presented by the Mayor of the city with an illuminated address in recognition of his services for many years.—Mr. A. J. Pollard, L.R.C.S., L.R.C.P. Edin., L.F.P.S. Glasg., of Armley, has been presented with a silver cigarette case in recognition of his services as instructor on First Aid to the Injured by the members of the Holbeck Division of the St. John Ambulance Association, North-Eastern Railway Company, Leeds.—On Dec. 1st, at the Bristol Council Chamber, the Mayor (Sir R. Symes), in the presence of a number of ladies and gentlemen, presented Mr. and Mrs. Richardson Cross with a silver cradle in recognition of the fact that a daughter had been born to them during the term of Mr. Cross's office of High Sheriff of Bristol. The cradle was engraved with the city arms and also those of the recipient. Accompanying it was a silver kettle.—At the annual meeting of the Swindon branch of the St. John Ambulance Association, after the distribution of certificates and medallions, the president, on behalf of the class, presented Mr. G. Rodway Swinhoe, L.R.C.P. Lond., M.R.C.S. Eng., with a liqueur case in appreciation of his services as honorary lecturer.—Last week Mr. Alan Eskrigge Carruthers, M.A., M.B., B.C. Cantab., &c., of Batheaston, Bath, was presented with a clock subscribed for by 50 parishioners as a mark of esteem on the occasion of his marriage.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BERKELEY, COMYNS, M.B., B.C. Cantab., M.R.C.P., has been appointed Physician Accoucheur for the Western General Dispensary, Marylebone-road, London.

BRICKWELL, J., M.R.C.S., has been re-appointed a Medical Officer for the Stoke Pogis Sanitary District of the Eton Union.

COLLINS, J. A., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed a Medical Officer for the Castor Sanitary District of the Peterborough Union.

CULMER, JOHN J., M.R.C.S., L.R.C.P. Lond., has been appointed an Assistant Surgeon for the New Providence Asylum at Nassau, Bahamas.

DIBBS, W. S., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Medical Officer for the Farnham Royal Sanitary District of the Eton Union.

DOBSON, J. F., M.B. Lond., has been appointed Resident Casualty Officer for the General Infirmary, Leeds.

FENWICK, S. C. C., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the No. 10 Sanitary District of the Parish of St. Mary, Lambeth.

FERGUS, J., L.R.C.P., L.R.C.S. Edin., has been appointed a Medical Officer for the Appleton Wiske Sanitary District of the Northallerton Union.

GAMAN, F. R. S., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer of Health by the Caistor Rural District Council.

GERMAN, A. W., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the First Sanitary District of the West Derby Union.

GOUGH, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed a District Medical Officer by the Northwich Rural Council.

GRAHAM, W., M.B., Ch.M. Glasg., has been appointed an Assistant Medical Officer for the Walton Workhouse of the West Derby Union.

GRIFFITHS, J. C., B.Sc. Lond., M.B., L.R.C.P., M.R.C.S., has been appointed a Medical Officer for the Tealby Sanitary District of the Caistor Union.

HILLS, W. C. D., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Twelfth Sanitary District of the Wisbech Union.

LISTER, W. T., B.A., M.B., B.C., F.R.C.S., has been appointed an Assistant Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road, W.C.

O'GORMAN, M. C., L.R.C.P., L.R.C.S. Irel., has been appointed a Medical Officer for the Arklow District.

PEET, HENRY, M.B. Lond., has been appointed Resident Medical Officer for the Brownlow Hill Workhouse Infirmary, Liverpool.

ROBERTS, E. A., M.D. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health for District No. 20, which includes the Parish of Clapham and a portion of Lambeth.

RUSSELL, J. RISIEN, M.D., F.R.C.P. Lond., has been appointed Assistant Physician to the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, Bloomsbury, London, vice W. S. Colman, resigned.

SHARPE, C. H., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer for the Second Oldbury Sanitary District of the West Bromwich Union.

SIMPSON, G. W., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Lamberhurst Sanitary District of the Ticehurst Union.

SOUTHEY, A. J., M.R.C.S., has been re-appointed a Medical Officer by the Eton Guardians and Rural District Council.

STEWART, J. PURVES, M.A., M.D., M.R.C.P., has been appointed an Assistant Physician to the Westminster Hospital, S.W.

STURROCK, A. C., M.B., C.M. Edin., has been appointed a House Surgeon for the Grimsby and District Hospital, vice H. S. Beadles, resigned.

SUTTON, W. L., has been appointed an Analyst for the Borough of Bury St. Edmunds.

TUNNICLIFFE, F. W., M.D., M.R.C.P., has been appointed an Assistant Physician for Out-patients to the Victoria Hospital for Children, Chelsea.

WALKER, D. E., M.B., C.M. Edin., has been appointed a Medical Officer for the Second Sanitary District of the Brixworth Union.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident House Surgeon. Salary £50, with board and washing.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN, Birmingham.—Resident Surgical Officer. Salary £50, with board, washing, and attendance at the institution.

BOROUGH OF WEYMOUTH AND MELCOMBE REGIS, Dorset.—Analyst. Salary £20 a year. Applications to the Town Clerk, Municipal Offices, Weymouth.

BURY INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board, residence and attendance.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary commences at £100 per annum, with prospect of increase to £250, with furnished apartments, board, attendance, and washing provided.

COUNTY HOSPITAL, Ryde.—House Surgeon. Salary £50 per annum, with board, lodging, &c.

GENERAL INFIRMARY AT GLOUCESTER, AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeoncy for six months. Board, residence, and washing provided.

GUEST HOSPITAL, Dudley.—Assistant House Surgeon for six months. Salary at the rate of £40 per annum, with residence, board, and washing.

HORTON INFIRMARY, Banbury.—House Surgeon and Dispenser. Salary £60 per annum, with board and lodging.

HOSPITAL AND DISPENSARY, Newark-upon-Trent.—House Surgeon, unmarried. Salary £80 per annum, with board and lodging in the hospital.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physician.

Digitized by Google

KINGTON UNION.—Medical Officer for the Kinsham District. Salary £30, with the additional payments authorised by the Order of the Poor-law Commissioners. The appointment is subject to statutory deductions. Applications to the Clerk to the Guardians, Kington, Herefordshire.

LEICESTER INFIRMARY.—Honorary Assistant Physician.

LIVERPOOL NORTHERN HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with residence and maintenance in the house.

LONDON LOCK HOSPITAL, 91, Dean-street, W.—House Surgeon for the Male Hospital. Salary £50 per annum with board, lodging, and washing. Applications to the Secretary at Harrow-road.

MIDDLESEX HOSPITAL, W.—Bacteriologist to the Hospital and Medical School. Salary £100 and fees for special classes.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, London. — Three Assistant Physicians in the Out-patient Department, for two years.

NORFOLK AND NORWICH HOSPITAL.—Honorary Dental Surgeon.

NORTHERN DIVISION OF SOUTH UIST PARISH.—Medical Officer and Public Vaccinator. Salary £77 10s., and private practice. Applications to Mr. T. Wilson, Solicitor, Lochmaddy, Clerk.

NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Fitzroy-square, W.—Clinical Assistant for the Central Out-patients' Department, Fitzroy-square, W., for six months. Honorarium at the rate of £35 per annum. Applications to the Secretary, Offices, 41, Fitzroy-square.

PADDINGTON-GREEN CHILDREN'S HOSPITAL, London, W.—Surgeon to Out-patients.

ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY, Wigan.—Junior House Surgeon for twelve months. Salary £80 per year, with apartments and rations, exclusive of wines, spirits, and washing.

WORCESTER COUNTY AND CITY ASYLUM, Powick.—Assistant Medical Officer. Salary commencing at £100 a year, with board, lodging, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £150 a year, with furnished apartments, coals, and gas.

Births, Marriages, and Deaths.

BIRTHS.

CHEESMAN.—On Dec. 11th, at Shohola, Swanage, Dorset, the wife of Edward R. R. Cheesman, L.S.A., of a daughter.

EWART.—On Dec. 8th, at 58, Queen's Gate-terrace, the wife of Dr. Chas. Ewart, of a son.

HUDSON.—On Dec. 8th, at Vine House, Cobham, Surrey, the wife of Arthur B. Hudson, M.R.C.S., L.R.C.P., of a son.

LANGFORD.—On Dec. 8th, at Weston-park, Crouch-end, N., the wife of C. Harris Langford, M.B. Lond., of a daughter.

MARRIAGES.

DURHAM—MAX GETZ.—On Dec. 15th, at the German Reformed Church, by Pfarrer Ehlers, at Frankfort-on-the-Maine, Frank Rogers Durham, youngest son of the late A. E. Durham, F.R.C.S., to Elisabeth Ottilie, youngest daughter of the late Geheimer Sanitätsrath Dr. Max Getz, of 43, Savignystrasse, Frankfort-on-the Maine.

MICHAEL—HARVEY.—On Dec. 7th, at St. Paul's, Upper Norwood, Cyril Eden Michael, M.A., M.B., B.C., M.R.C.S., L.R.C.P., to Ada Helen, widow of the late Henry N. Harvey, of Hayle, Cornwall.

DEATHS.

MINTER.—On Dec. 9th, at the Royal Naval Hospital, Plymouth, Ernest Denman Minter, Staff Surgeon, R.N., late of H.M.S. *Rupert*.

MYERS.—On Dec. 10th, 1898, at 31, St. Augustine's-road, Camden-square, N.W., Elizabeth Beaufoy Myers, widow of the late Robert Short Myers, Surgeon, whom she survived upwards of 39 years, in the 87th year of her age. No flowers, by request.

ROGERS.—On Dec. 11th, at Old-street, Finsbury, E.C., J. F. Rogers, L.R.C.P. Edin., M.R.C.S., aged 63 years.

WOOD.—On Dec. 7th, at Cranbrook, Kent, Henry Benjamin Wood, M.D., aged 69.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (9.30 A.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.), London Throat Hospital (2 P.M.).

TUESDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.), Royal Ear Hospital (3 P.M.).

WEDNESDAY (21st).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat Hospital (2 P.M.).

THURSDAY (22nd).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex, (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.).

FRIDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St, Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.) Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.) London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (24th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (20th). — PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. E. F. Trevelyan: (1) A Cyst on the Third Ventricle; (2) A Cyst on the Fourth Ventricle; (3) An Anomalous Tumour of the Brain.—Dr. H. M. Fletcher: Peculiar Condition of the Colon in Pernicious Anæmia.—Mr. Crosse and Mr. Pakes: Black Water Parasite Alive.—Mr. Pakes and Mr. Howard: The Technique of Blood Films.—Mr. H. B. Robinson: Multilocular Tumour from the Inguinal Canal of a Female.—Dr. C. D. Green: Extensive Sarcoma of Mediastinum. Card Specimens:—Dr. Trevelyan: (1) Renal Tumour; (2) Heart with Extensive Calcification of Mitral Valve; (3) Suppurative Typhoidal Cholecystitis; (4) Foreign Body from Peritoneum.

CHELSEA CLINICAL SOCIETY (Holy Trinity Parish Hall, Pavilion-road, S.W.).—8.30 P.M. Dr. C. C. Gibbes: Early Diagnosis of Mitral Stenosis, with cases.—Mr. J. D. E. Mortimer: A Case of Delirium Tremens treated by Inhalation of Chloroform.—Mr. C. A. Morris: Intestinal Obstruction due to Gall-stones.

WEDNESDAY (21st).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—7.30 P.M. Exhibition of Binocular Microscopes.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Gt. George-street, Westminster, S.W.).—7.30 P.M. Papers:—Capt. A. Carpenter: The West Indian Hurricane, September, 1898.—Mr. W. H. Dines: The Connexion between the Winter Temperature and the Height of the Barometer in North Western Europe.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (20th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-sq., W.C.).—3.30 P.M. Dr. Colman: Syringomyelia.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street, W.).—4 P.M. Dr. H. Campbell: Cases of Paraplegia and Remarks on Treatment.

THURSDAY (22nd).—LONDON TEMPERANCE HOSPITAL.—2 P.M. Dr. S. Fenwick: Clinical and Pathological Demonstration to Senior Students.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE DIRT OF THE FARMER AND ITS DANGER TO MILK-SUPPLY.

A COUNTRY correspondent sends us the following disagreeable picture of the circumstances in which the milk-supply is obtained in the district where she resides:—"Cowsheds are dark, damp, and crowded; the ventilation is poor; the stench thick, hot, and heavy; the bedding of cows is scanty and hardly ever renewed; the drainage bad. The animals lie on moist bedding and get caked with manure both sides of their bodies; their udders are also caked with it. During winter they are shut up for months at a time, only walking to a trough (once or twice a day) in their yard to drink. They have no exercise all these months. Being thickly clothed in hair and naturally out-door creatures the imprisonment debilitates them, causes disease, and many die during calving in the spring; their milk becomes thin. Cowsheds should be better drained and ventilated; there should be windows that will open on the south side of every one of them in such a position that the sunlight will stream in upon each cow and upon its bedding. Stables are hardly ever built without windows, and yet horses, in my opinion, are not as valuable creatures to mankind as cows. If there are not windows in fowl-houses poultry suffer from disease. Cows should be made to walk along a road for a mile every day during all the worst days of their winter imprisonment. Milk is defiled by the hands of milkers and the extraneous matter found in it comes from the hands of the men who milk the cows. Cow-boys and farmers have the dirtiest employments possible. They attend to cows calving and to sheep and pigs and horses, and constantly cart manure about. All their implement-handles are caked with filth of every sort, but they never wash their hands before going to milk. Their hands are quite a loathsome sight, so caked and brown and hard are they with dirt. They have to soften them when milking by rubbing them together with milk and then they continue to milk, their hands dripping with blackened milk. I have been told this by several observers. These men also go out to milk from homes where members of their families have fevers of all sorts, though I am aware of the order that they are not to do so. Fathers, mothers, and brothers of children suffering from infectious diseases go to milk cows. They also suffer from all sorts of terrible things themselves and their filthy hands convey the diseases not only to the udders of cows and infect them, but to the milk, and yet the bodies of milkers are never inspected! These men never wash, such a thing as a bath is never taken by any farmer, any member of his family, or any labourer, they only wash their faces on rising in the morning. Farmers ought to be made to provide soap at the farmyard trough or pump, and to see that milkers wash their hands before they go to milk twice a day. The employers should be made to provide a bath in some shed and to see that each labourer has a bath every Saturday night. A farmer should be fined (under the Adulteration Act) if any extraneous matter is found at the bottom of his milk-cans. There is a very great fuss made about drains and quite rightly so, but ninety-nine-hundredths of the milk consumed never enters any dairy whatever. It is first of all milked into a tin pail (in winter in a cowshed and in the summer in the field) and it is on the spot poured into a tall milk-can which has a cover to it and the contents of which are never meddled with at all till it arrives either by cart or train at the shop or station where the milkman who buys it of the farmer empties it into his own large cans and it is taken round to customers at once."

THE HOUSE SURGEON'S FEES UNDER THE EMPLOYERS' LIABILITY ACT.

To the Editors of THE LANCET.

SIRS,—Will you kindly give me your opinion upon the following? A man was admitted to this institution suffering from an injury sustained while at work. Some time after a medical man called to find out the nature of the injury and probable date of discharge, stating that his inquiry was in connexion with "The Workmen's Compensation Act." I declined to give any information and said I was quite prepared to furnish a report. Would you kindly state if I was acting correctly? I should be very sorry to do anything which would give a brother practitioner just cause to complain of my conduct towards him, but it seems to me that it is *ultra vires* to expect me to supply information gratis for which formerly I should have received a fee. If, however, you think that such information should not be withheld I shall be very pleased to apologise to the gentleman in question and tell him all he wants to know.

I am, Sirs, yours faithfully,

Dec. 7th, 1898. HOUSE SURGEON.

*** Our correspondent is under no legal obligation, so far as we know, to give information.—ED. L.

A "BLOWER" FOR CAPILLARY TUBES.

A CORRESPONDENT asks us what is the best apparatus to expel vaccine lymph from the tube. A sample of artificial blower for expelling lymph from capillary tubes has been submitted to us by the Jenner Institute for Calf Lymph, 73, Church-road, Battersea, S.W. The institute gives these blowers to any practitioner who cares to apply for one. The glass tube is packed with carbolised wool to arrest any suspended dust in the air passing through it. We have tested the sample sent to us and find it efficient.

ALLEGED ILLEGAL OPERATION BY A NURSE.

ON Dec. 7th Jane White, described as a nurse, was charged at the North London police-court with causing the death of a woman named Angelinetta. Inspector Drew gave evidence of the arrest on a charge of having performed an illegal operation. The prisoner was cautioned but said that she had done nothing illegal. She acknowledged that she knew Angelinetta and that she had had some pills from her (White). Inspector Drew searched the room and found two catheters, one wet with blood. This White admitted having used upon another woman. He also found pills, two more catheters and some forceps. Angelinetta died on Nov. 25th, the certificate stating that she had died from peritonitis following a natural miscarriage. The body is to be exhumed and the prisoner was remanded in custody.

A CHEMICAL IOTA.

To the Editors of THE LANCET.

SIRS,—In experimenting upon oil of eucalyptus lately I noted a few tiny facts. Of these the following may prove useful here and there if you think them worth printing in THE LANCET:—1. A section of india-rubber tubing put into the oil expands in less than 24 hours to about double its size. Upon withdrawal reduction commences and the original size is reached in 2 or 3 days. But if steeped in methylated spirits to extract the oil reduction becomes far advanced in about half an hour. If it be desired to pass a bit of tubing over anything having a diameter as great as or greater than its own, dip the tube-end in the oil for a minute or more and it can then with far less difficulty be made

Digitized by Google

to cover the object. This fact may be of use in the laboratory and elsewhere for a variety of purposes. Expansion also occurs if the rubber be placed in oil of turpentine or in paraffin lamp oil 2. Eucalyptus oil dissolves iodine in all proportions; thus liquor iodi fortis can be readily produced. So made it paints on the skin less evenly than when the oil and methylated spirits are used in equal quantity. The oil does little to remove recent iodine stains from the skin; but if, after using it, methylated spirits be rubbed on a distinct lessening of the stain results. 3. A little sublimed sulphur heated in the oil in a test tube becomes a pretty fluid globule bright yellow and mobile. On boiling for a second or two the globule dissolves and then the smell of H_2S is swiftly given off. I have not tried the solvent powers of this fluid, but I may add that as it cools the sulphur therein returns to the state of powder. I kept specimens of healthy and of albuminous urine in test tubes for several weeks last summer without decomposition by covering each specimen with a layer of eucalyptus oil as thick as a shilling. I am, Sirs, yours faithfully,

Devonshire-street, Portland-place, W., Nov. 30th, 1898. E. DIVER.

JUDICIAL WIT.

HIS HONOUR JUDGE BACON has a reputation not altogether undeserved of being the "funny man" among county-court judges. This being so we are sorry to see him deliver himself in such a manner as is credited to him in the *Daily News* during the progress of a case tried before him on Dec. 8th. The plaintiff, a widow, brought an action against a baker for damages received by falling through the baker's coalhole, the covering parts of which had been left unfastened. Mr. Frederick J. Oxley said, according to the report in the daily press, that plaintiff had suffered from an attack of bronchitis induced by the shock. The lung was really a continuation of the bronchial tubes. Judge Bacon: "Oh! is it? Well, as a member of the College of Physicians you ought to know better than I do." We quite agree with Judge Bacon here, but as he holds such sound views why did he go on to say that "he could not accept without further evidence the statement of the doctor that bronchitis—which was something outside the system—could be induced by shock as gout might be. Gout was undoubtedly something within the system." What does his honour mean by "system" and why is bronchitis outside it, whatever "it" may be?

THE USE OF THE CAT.

AT Warwick on Dec. 8th the grand jury made the following presentment before Mr. Justice Mathew: "To the Hon. Sir James Charles Mathew. Warwick, Dec. 8th, 1898. The grand jury unanimously make presentment that, in view of the great and increasing number of cases at the assizes of criminal assaults on women and children, it is desirable and in their opinion necessary that Her Majesty's judges should be empowered by law to order corporal punishment in addition to any other that they may inflict in all cases in which in their opinion the evidence justifies it." His lordship said that he would forward the presentment to the Home Secretary but that it would not obtain his (the judge's) support.

"THE COLOUR OF NEWLY-BORN NEGRO CHILDREN."

To the Editors of THE LANCET.

SIRS,—With reference to the correspondence which has appeared in THE LANCET of Dec. 10th as to the colour of newly-born negro children I wish to endorse the statement of "Guiana." During four years' service in West Africa I delivered seven or eight negro women and in all cases the colour was that of a light quadroon. In two cases the children looked remarkably white but after a week the colour gradually changed and it would appear that atmospheric conditions were requisite to produce the full black colour of the negro. In three or four months the children were of copper tint and after a few years the change to black was complete. I further observed that the hair was somewhat straight, rather like that of the Hindoo, but its "woolly" character became evident in a few weeks.

I am, Sirs, yours faithfully,

D. J. MACCARTHY, late Gold Coast Medical Staff.

Dec. 13th, 1898.

PAY WARDS.

To the Editors of THE LANCET.

SIRS,—I shall feel very grateful if any of your readers will kindly favour me with information respecting the methods by which charity hospitals with "pay wards" in England are remunerated for medical or surgical services. Here, in the United States, I believe such institutions (and they are quite numerous) exact a certain sum for board, room, and nursing, allowing the honorary physician or surgeon to fix his own fee which, of course, is pocketed by him. This system is extremely advantageous to the honorary staff but very unfair, illiberal, and undemocratic to those practitioners in the neighbourhood who do not hold hospital appointments. Less fault might be found with the system if any reputable physician in the vicinity were accorded similar privileges, but there are few managers so charitably disposed. At best, however, it is a crude anomaly to witness two classes of patients under the same roof—one for sweet charity, the other for sordid gain. Pay-patients should be relegated to private hospitals and none but the poor should be admitted to those institutions which owe their origin and existence to the charity of the public.

I am, Sirs, yours faithfully,

J. HARRIS JONES, M.D. Brux., &c.

Wilkes-Barre, Pennsylvania, Nov. 23rd, 1898.

SENTENCE FOR ASSAULTING A DRESSER.

AT Southwark police-court on Dec. 9th Charles Pilford, a stall-keeper, was sentenced to two months' hard labour for assaulting his wife and to fourteen days' hard labour for assaulting Mr. E. Goble, a dresser at Guy's Hospital. The prisoner had beaten his wife so severely that she had to be taken to the hospital to have her injuries attended to. He accompanied her and behaved in an outrageous manner in the surgery. Mr. Goble requested him to leave whereupon Pilford struck him twice in the face. We must say for the credit of the class that generally frequents public hospitals that it is very rare for either a patient or the friends of a patient to behave otherwise than well. When, however, they do offend it is an offence which cannot be lightly passed over.

"IL FAUT SOUFFRIR POUR ÊTRE BELLE."

THE London correspondent of the *Sheffield Daily Telegraph* states, according to an editorial paragraph in the issue of Dec. 9th, that a well-known society beauty has just had the "outer skin of her face removed with a view of renewing her complexion." The operation is not only "painful but tedious, because it is done by pin-prick, as one may say. The whole of the outer skin is removed in this way, and if the operation is successful the patient emerges with a face of bewitching brilliance. That is the result of the present case. ..... Few people know, but anyone can see that her complexion has been remade. ....." We must congratulate the editor of the *Sheffield Daily Telegraph* upon possessing a correspondent who exhibits such enterprise. The story is as pretty as the new face.

WANTED A HOME FOR A RESIDENT LUNATIC.

To the Editors of THE LANCET.

SIRS,—I should feel obliged by you or any of your readers informing me where in this district an insane patient can be received. The patient's husband is prepared to pay to the amount of two guineas a week. I am, Sirs, yours faithfully,

Boston, Lincs., Dec. 13th, 1898. J. WELSH, L.S.A. Lond.

A MISLEADING ADVERTISEMENT.

A CORRESPONDENT sends us the following cutting from the *Queen* of Dec. 3rd, p. 979:—

> "A graceful figure can be achieved by using the Amiral Soap for reducing corpulency by external local application. Recommended by the medical profession and the 'Lancet.' No diet. No discomfort. To be obtained through all chemists, or direct from the Amiral Soap Syndicate, 28A, Basinghall-street, E.C., on receipt of 8s. for box of two tablets. Pamphlet and copy of testimonials on application. West End depôt, 20, Brook-street, W.—[Advt.]"

"Surely it can't be true" is his comment. He is right. We have not recommended "Amiral" Soap. What we did say will be found in THE LANCET of July 30th, 1898, p. 266.

Floating Kidney.—In a few cases a pad and abdominal belt will give decided relief in floating kidney, but in most of the cases very little benefit is felt; unfortunately it is not possible to say beforehand whether this pad and belt will do good, so in any case in which an operation is undesirable it is well worth while to try a belt. In applying the belt it requires to be of a particular degree of tightness to give the most comfort.

Memo.—There are so many books upon the subject that our correspondent had better consult the list given in THE LANCET of Sept. 3rd, 1898. Perhaps we might recommend as an elementary work "Elementary Practical Bacteriology," by Kanthack and Drysdale; Macmillan and Co., price 4s. 6d. Another good book is "The Principles of Bacteriology," by Dr. A. C. Abbott.

Treatment.—We do not give medical advice. If, as we understand, our correspondent is a medical student he should have no difficulty in finding a qualified man to enlighten him.

Mr. Furner's communication was duly received.

During the week marked copies of the following newspapers have been received: *Manchester Courier, East Anglian Daily Times, Bradford Observer, Croydon Guardian, Rochdale Observer, Rangoon Times, Penrith Observer, Rugby Advertiser, Lichfield Mercury, Pioneer Mail, Architect, Times of India, Ayr Advertiser, Eastern Morning News, Yarmouth Advertiser, Builder, Citizen, East Sussex News, Scotsman, Liverpool Daily Post, Warwick Advertiser, Western Morning News, Kenilworth Advertiser, Auckland Chronicle, Blackpool Gazette, Scarborough Mercury, Birmingham Gazette, Ossett Observer, Cambs Times, Portsmouth Times, Yorkshire Post, Irish Times, Leeds Mercury, Brighton Gazette, Derby Mercury, Duffield Observer, Cheltenham Examiner, Hastings Times, Bristol Mercury, Abingdon Herald, Norwich Journal, Dereham Times, Echo, Daily Chronicle, Sanitary Record, Mining Journal, City Press, Reading Mercury, Local Government Chronicle, Hertfordshire Mercury, Weekly Times and Echo, Bulawayo Chronicle, Surrey Advertiser, Local Government Journal, Public Health, Kentish Express, Public Opinion, Friendly Societies' Recorder, Lincoln Leader, South-Western Comet, Bridport News, Barrow Herald, Doncaster Gazette, Maidstone Journal, Berkshire Chronicle, Louth and North Lincolnshire Advertiser, &c., &c.*

SQUIRE'S CHEMICAL FOOD.

Known for 30 years as the best preparation of its kind

FOR DELICATE CHILDREN.

Long experience has shown that, when properly diluted, it is not a source of danger to the teeth, and, being a fluid, it is readily assimilated.

SYRUP OF SENNA.

A mild Aperient for Children, pleasant in flavour. Since its introduction, a quarter of a century ago, has been in continuously increasing demand.

CONFECTIO BELÆ RECENTIS.

A valuable remedy in Chronic Diarrhœa and Dysentery. Prepared in this country from Bael Fruits, which are imported in their fresh and natural condition.

DOSE—A Teaspoonful.

"It possesses all the aroma of the fruit, and is not only astringent where diarrhœa exists, but possesses the singular property of being aperient if the bowels be irregular or costive."

"Messrs. SQUIRE'S preparation is all that can be wished."—THE LANCET.

KASAK ELIXIR.

A Tonic Laxative — reliable, palatable, uniform in strength — without constipating reaction.

DOSE—For a Child, one or two Teaspoonfuls (according to age) at bedtime or in the early morning.

For an Adult, one Tablespoonful.

ALSO

KASAK PILULES. KASAK CAPSULES.

LIQUOR MORPHIÆ BIMECONATIS.

PANOPEPTON.

PANOPEPTON

is the entire edible substance of prime lean beef and best wheat flour, thoroughly cooked, properly digested, sterilised, and concentrated in vacuo, and preserved in a sound sherry.

PANOPEPTON

is the food par excellence for invalids; in all acute diseases, fevers, &c.; in convalescence, for the large class of persons who, from feebleness or deranged digestion, or antipathy to ordinary foods, require a fluid, agreeable, and quickly assimilable food.

PANOPEPTON

proves an effective resource against sleeplessness when this is due to excessive fatigue, stress of mental work, or malnutrition.

PANOPEPTON

is at once a grateful stimulant and food.

PANOPEPTON

should not be mixed with milk or any other food, but should be taken pure or with plain, iced, or aerated water. For an adult, the usual portion should be a dessertspoonful to a tablespoonful several times a day and at bedtime.

Supplied to the Medical Profession in 6-oz. and 12-oz bottles, at 2s. and 3s. 4d. each.
Specimen and Pamphlet will be forwarded on request.

The Harveian Lectures

ON

DISEASE, ITS TREATMENT AND THE PROFESSION OF MEDICINE IN 1899.

Delivered before the Harveian Society of London on Dec. 1st, 8th, and 15th, 1898,

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND JOINT LECTURER ON MEDICINE TO THE MEDICAL SCHOOL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

LECTURE II.[1]

Delivered on Dec. 8th.

THE MODERN ADVANCES IN TREATMENT AS THEY AFFECT THE PUBLIC AND THE PROFESSION.

Introduction.—Surgery and its Influence on Therapeutics.

GENTLEMEN,—I propose to-day to place before you: (1) the progress of therapeutics; (2) the means which they employ, including the supply of drugs and their use and the facilities for the treatment of the sick; (3) the general principles underlying our modern treatment; and (4) the attitude of the public and of the profession in relation to matters of treatment. The changes which have occurred in the treatment of disease are not inferior to the advances in pathology and one of the greatest is the extension of the clinical domain of surgery. Thus conservative surgery and visceral surgery, the diagnosis of disease by exploration, and its surgical treatment by direct manipulation, must occupy the foreground of any review of our recent progress. Surgical art may be said to have attained its ideal when the mechanical cure of disease becomes possible. Abdominal exploration is the most important of all the additions to our surgical resources, which also include the exploration of joints and the illumination of various internal cavities and their local treatment. Not many years ago lives were sacrificed daily to the impossibility of establishing the diagnosis of actual suppuration in the abdominal cavity. To operate on an abdomen where an extensive abscess had not yet formed did not enter the professional mind in those days and the idea of laparotomy for the sake of ascertaining that no abscess existed there was to it as foreign as are to us the thoughts of dwellers in distant planets. The whole anxiety was lest an operation should be attempted whilst pus had not been proved to exist. Most of the cases operated upon died because gangrene and suppuration had proceeded too far before they were revealed by physical signs. These fatalities are now the exception. Physicians have a further debt to acknowledge in the influence which surgical methods have exercised over medical therapeutics in the direction of definiteness in diagnosis and of thoroughness in treatment.

The medico-chirurgical idea in therapeutics.—The relation between the work of the physician and that of the surgeon is one of ever-increasing harmony. There can be no better surgeon than he who is also a physician, and the best physician is one with a practical knowledge of surgery. The division of labour between medical and surgical practice is therefore a necessity of the artist rather than of the art. The spirit of our treatment is becoming more and more identical to our mutual advantage. Hospital physicians find themselves day by day bestowing more time and thought upon the study of cases which it is given to others to cure and upon the discussion of methods which the surgeon may carry out. Some of this work and thought may perhaps not be wasted from a surgical standpoint, since in many cases our aim is to reduce the treatment to a surgical question. All specialists are also guided by the same medico-chirurgical idea, and it is given to some of them to carry it out in its entirety. The limitation of their field of work facilitates its cultivation in every direction, surgical as well as medical. Gynæcology, as it is now practised, is a microcosm of surgical and medical practice combined.

[1] Lecture I. was published in THE LANCET of Dec. 17th, 1898.

MEDICAL QUESTIONS OF TREATMENT; OUR THERAPEUTICS, PAST, PRESENT, AND FUTURE.

Turning to medicine we find a progress equally important though not so fully recognised and to this two opposite tendencies have contributed: scepticism, which led to the temporary adoption of the expectant treatment, to the gradual and permanent abandonment of irrational prescriptions, and to the recognition of *vis medicatrix naturæ;* and the experimental method applied to therapeutics, now a science in itself, that of pharmacology.

Scepticism in therapeutics.—For a blind belief in drugs and in systematic polypharmacy we must look back for more than 100 years. Scepticism had existed from earliest antiquity but it had never prevailed. Early in this century, however, there came a wave of scepticism stronger than any before. Strangely, homœopathy, while it shattered the old belief, made claims upon our credulity greater than any superstition. It failed to build up any lasting medicinal system though it called attention to some unutilised drugs and modified our opinion of the mode of action of some of the older ones; but the practical service which it did render was to direct attention to the importance of studying the resources of nature and of adapting diet to her requirements. Owing partly to this influence and chiefly to the scientific search for strict evidence of the alleged action of drugs expectant treatment became for a time the last word of medical art. Drugs were discredited and it was thought that the only safety lay in allowing nature free scope.

Rational treatment.—This paralysing form of scepticism is now dead. The advances in etiology and in diagnosis rapidly revived the hopefulness of the physician by directing his aims towards definite objects, whilst the doctrine of discouragement was soon forgotten by the patients with whom scepticism has never found much favour. Treatment having learnt to strike at the cause was henceforth to be styled rational. The action of the more potent remedies was recognised and studied, and the advantages originally due to empirical treatment were utilised once more and turned to better account. Physiology, as it threw more light upon the mechanism of the healthy functions, tended to explain their deviations and to suggest how these might be rectified. In this relation physiology is another word for preventive medicine and for hygiene and public health, subjects which ultimately found their place as specialities in our therapeutics, and to it is also due the elaboration of the physiological principles of treatment and of prevention. In presence of these definite results the scepticism of to-day is a very different one from any which had preceded. The efficacy of agents such as quinine, mercury, or iodide of potassium appeals to the common sense even of the believer in infinitesimals and the medical sceptics as to vaccination are an extinct race. Since the physiological effect of individual drugs has become matter of demonstration it is no longer the power of medicinal agents which is doubted by some, but the wisdom of utilising that power lest it prove to be a double-edged weapon, as in the case of the narcotics and of other drugs.

Symptomatic treatment.—But the majority, whilst recognising as paramount the rational treatment of the cause, feel no scruple in dealing with its manifestations. Favoured by closer clinical observation this tendency is now a leading feature in practical therapeutics. Each symptom becomes a fresh opening for treatment. Greater than any perhaps has been the influence of clinical thermometry which we owe to Wunderlich. The suppression of pyrexia, apart from its cause, has been pursued as a definite object. To name but a few other symptoms among the most important, insomnia, the neuralgiæ, increased pulse-tension, cardiac depression and excitement have been singled out for treatment by special drugs. Symptomatic treatment, however, could hardly have grown to its present importance but for the extraordinary supply of new remedies each possessed of some prominent virtue and therefore put forward as special remedies for separate symptoms. Chief among these groups of "symptomatic" drugs are the antipyretics, the hypnotics, the analgesics, the anti-spasmodics, the cardio-vascular depressants, and the cardiac stimulants. Whilst therapeutics themselves are becoming more rational an exclusively symptomatic treatment is increasingly patronised, often independently of the physician, by the public and by the pharmaceutist, and in this there is a danger.

Polypharmacy and monopharmacy.—Polypharmacy in its extreme form has had its day and monopharmacy is now gaining in favour. The combination of drugs—skilful, efficient,

Digitized by Google

and artistic—had been regarded as the highest fulfilment in practical therapeutics. Was this a fundamental mistake? The view that drugs may be of use severally in their different ways, although administered simultaneously, is countenanced by the beneficial results of a mixed diet, but this analogy illustrates also the detrimental effect of any excessive complication. Clinical observation also supports the belief that drugs may act beneficially even when combined and some of these combinations have received the practical sanction of experience—as, for instance, the combination of digitalis and strychnine or of digitalis and iron.

Monopharmacy, now in the ascendant, has lately been reduced to its simplest expression, the use of a single principle taking action upon a single morbid factor. But in a less exclusive degree of monopharmacy, that of the separate administration of any one vegetable drug, there is almost always something of polypharmacy since the various principles contained in each drug are often dissimilar in their action. This is shown in cases of idiosyncrasy by an intolerance for the drug, although some of its chemical constituents may be severally well borne. The isolation of the active principles of each drug and their separate administration represents a much more advanced stage of monopharmacy, the rapid development of which we owe to modern chemistry. This is from the standpoint of treatment by no means a final stage. Even when administered singly the isolated principles of drugs have multiple organs to act upon the organic functions of which may react differently to them; and as in the familiar instance of morphia the therapeutic dilemma is often how to help one of the functions without harming the others. It is now possible in some cases to single out the morbific agent as well as the remedial principle. This fulfilment is the fruit of bacteriology which has provided us with toxins and antitoxins addressing themselves directly to the cause of the disease.

Both methods are still prevalent.—Great as was this advance its sphere of operation remains limited and generally we have to employ less elemental agents. Not infrequently we are obliged to mix our principles after isolating them, as in the case of morphia and atropine and of iodide of potassium and arsenic, and some of us are guilty of even worse polypharmacy. Both tendencies are represented in our contemporary practice and in the growing supply of two opposite sets of pharmaceutical preparations. Pharmaceutical ingenuity has favoured the administration of separate drugs by wrapping up or compressing those which are unpalatable without the addition of any flavouring excipients. To such an extent has this facility been carried that the prescribing function of the physician and the dispensing function of the chemist have been appreciably restricted. On the other hand we are provided with compound medicines of great complexity which doubtless owe their popularity with the patients as well as with their advisers to the excellence of their form. This is a tribute to the usefulness of a well-planned polypharmacy and to its recognition by a large section of the profession.

The art of prescribing and its modern neglect.—The changes which these advances have wrought in professional practice are great and obvious. One of them—the growing neglect of individual prescribing—may be regarded as unfortunate. This neglect is at its origin traceable to the schools and the need for reform in this direction is urgent. If imperfectly trained in prescribing the young practitioner would the more easily take to the use of ready-made preparations. Push this tendency to an extreme and it would result that the art of prescribing would pass into other hands. Without sacrificing the convenience afforded by an improved supply of suitable compounds an effort might perhaps be made to educate the future practitioner to greater independence in selecting for himself his therapeutic agents. One of the advantages of personal prescribing is the opportunity afforded for adapting the remedies to the individual case and for constantly readjusting them to its changing needs. The worst form of polypharmacy is that which excludes variety. Change is the essence of symptomatic treatment and the art is to save fatigue and disgust for the patient whilst avoiding the cumulative action of drugs and their gradual loss of effect. The systematic rotation of drugs instead of their continuous administration may be suggested as a means of combining grateful variety with the maximum effect from the remedies prescribed. Opinion is divided as to the desirability of prescribing in the vernacular instead of in the old-fashioned Latin formulæ. This is one of our modern questions which deserves serious consideration. There are facts to guide us in the matter, but upon them I will not dwell.

Wholesale pharmacy and the question of dispensing.—The modern innovations in pharmacy have affected both the practising surgeon and the pharmaceutists. To those engaged in country practice there is a saving of time, of responsibility, and of extraneous assistance. The dispensing chemist is better trained now than he was, but his work is simplified and the skill of his craft less often required. There is also less of the practical handling of the crude drugs, and this affects the question of apprenticeship. The wholesale manufacture of simple drugs, such as tinctures, infusions, and others, was but the first step to the wholesale manufacture of compounds. The dispensing chemist's occupation is curtailed; but this is not all. Wholesale manufacture means cheapness of production and the coöperative supply has further reduced his opportunities. The operation of these causes is a factor in a troubled question which lies beyond the scope of our present subject.

The old drugs and the new.—New remedies of undoubted efficacy have been added in the later editions of the British Pharmacopœia and outside the Pharmacopœia there is a yet larger supply; most of them, however, are palliative rather than curative agents and not free from the dangers of habit and of overdosing. I can only allude in passing to the large and important subject of organ-therapy, the idea of which we owe to Brown-Séquard and the merits of which are still awaiting the verdict of experience. Some brilliant results have been achieved, in particular in the thyroid treatment of myxœdema, but there has been much disappointment in other directions. The supply of toxins and antitoxins is still in the safe keeping of experts. The germs of disease have not yet been let loose, but the recent experience in Vienna teaches a lesson not easily forgotten. The bulk of our recent remedies are coal-tar derivatives and their number is constantly growing. Most of them are administered for the sake of the sleep which they promote or of the pain which they subdue; but we are not sufficiently informed as to the effect which they may take upon the tissues and functions. Freely advertised and prescribed they have become known to the public and their unauthorised and irresponsible use by the laity is one of the peculiarities of our time which has variously told upon the public, the profession, and the pharmaceutical branch. Alcohol has long stood at the head of the list of poisonous drugs to which the public has unlimited access. Its value is undeniable, but more than any other it is prone to establish a habit which lessens its effect and brings into play its destructive properties. Happily it is falling into discredit as a therapeutic agent. In the most acute forms of disease such as pneumonia, endocarditis, and in all conditions leading to exhaustion its free administration is indicated, but where the affection is subacute or chronic its continued use has rightly lost favour except as an addition to meals. The endeavour has been made from the side of total abstinence to show results equally good, if not better, from withholding alcohol even in the acute affections, but the suggestion based upon these observations has not so far obtained any general recognition.

Drug diseases.—Ether, morphine, cocaine, and the various hypnotics, anti-spasmodics, and anti-neuralgics, including antipyrin, antifebrin, and phenacetin, are the chief representatives of a dangerous group of drugs to which much injury to health is often due. Sudden seizures from an accidental overdose produce much alarm, though they may leave no permanent mischief. A greater evil is the gradual depression in health which may be induced by the daily use of some of these drugs. The weaker the patient the greater is his dependence upon the comfort which they confer; but their tendency is to confirm the neurotic habit, and the relief given to the pain is often the means of disguising its cause and of leading to delay in its being rationally treated.

THE CARE OF THE SICK.

Nursing.—The most important part of the physician's treatment is often that which is managed by proxy through his trained and efficient delegate and without her faithful coöperation the surgeon's operative skill might be in vain. From time immemorial the tending of the sick as a work of pure charity had been carried on by religious communities—by some of them as a special and sole object of their association—whilst the housing of the sick was provided by some of them and still continues to be—none better known to us than the sisters of charity who include within their ranks

Digitized by Google

women of high birth and education. But in this country it is within our own times that the science and art of nursing have risen to their high standard, combining the highest motives with the highest efficiency, thanks to the completeness and the discipline of hospital training and to the advanced teaching of the physician and the surgeon. But to Florence Nightingale our chief debt is due.

Hospitals and institutions.—A recognition of the advantages of hospital treatment not to be secured elsewhere except by the wealthy has led to the multiplication of hospitals for the relief of the poor who in this are better off than others, and also of paying institutions, where treatment is organised instead of having to be improvised and where professional services are not unrequited. For a large number of members of the middle-class who lead a solitary life or lack the necessary comfort nursing-homes of this sort are a necessity.

Isolation hospitals; notification and isolation.—The growing number of isolation hospitals and the strict notification of the acute infections are, from the standpoint of public health, improvements of unmixed advantage, but they tend to restrict the sphere of practice. For phthisis also a modified plan of isolation is being practically discussed. This is specially needed for the lower classes in our great towns and it is for them that suitable hospitals are mainly required. Private sanatoria for phthisis have long existed abroad in which the successful treatment of patients is assisted by constant care and supervision, but hitherto we had only had hospitals in the heart of towns where the modern treatment by open air is not provided. We are now to imitate the example of Germany and to provide homes for the less affluent among the middle class where modern methods can be applied, including the discipline which is necessary, though it may be felt to be more irksome in this country where every man is a king. Our greater task, however, concerns the masses whose aggregate of mortality from phthisis runs to very high figures. The only efficient way to protect the families of the poor is to remove the dangerous patients from their midst to sanatoria where the risk of infection can be fully controlled. The time may soon come when each large city is provided with suitable country isolation hospitals for phthisis. Our climate is proverbially unstable, but I believe that the tempering of the bleak winds is a problem which is not insolvable if the advantages of suitable site and soil and of adequate protection can be secured. Action of this sort which is now contemplated in Liverpool and elsewhere will lead the educated to greater carefulness in the limitation of the infection without any resort to notification or segregation.

The hospital question.—Are the really poor to be the only privileged ones in obtaining hospital treatment and nursing? Are these privileges to be denied to a much larger class who, whilst able humbly to contribute towards the hospital funds, cannot purchase the analogous facilities offered in private homes? To deny to some of those who are quite unable to secure it elsewhere by payment the attendance which is desired and to offer it free of all charge to a lower stratum of poverty would seem to be an uneven dispensation of charity. These difficulties are better known to those who administer than to those who support our hospitals. So long as there are no nursing homes for the poorer middle class where payments can be adapted to the means of each, patients possessing no social or financial claim to gratuitous treatment will occasionally be sent to our hospitals by their own medical attendants.

GENERAL THERAPEUTICS.

As a slight contribution to practical therapeutics I propose to consider briefly some of the broad principles which guide our treatment. A clearer insight into the mechanism of disease has infused greater directness into our methods. Modern physiology has taught us even more than pathology. But we have learnt most, perhaps, from watching in animals and in man the process of spontaneous recovery. These lessons are bearing their fruit. We do not despise the welcome aid of drugs and the opportune placebo, but we have turned to the cultivation of those forces which Nature herself supplies. How different this conception from the old idea that disease was a thing to be starved out of existence, strangled by violent remedies, or made to escape with profuse discharges of serum or of blood. No longer do we see the bleeding of the old days when, because it was spring or autumn, rich and poor flocked to the apothecary to be bled to the point of fainting. There was occasional good in bloodletting and in certain conditions of disease it is now being revived. It was its immoderate use which was so baneful. Our method differs entirely from that of the expectant treatment. Nature cannot always be safely left to herself. Interference, to use the word in an invidious sense, is to be avoided; but our intervention is often indispensable—as, for instance, when chronic obstructions finally lead to a deadlock. This deadlock is the climax of a long continuance of faulty or imperfect function. Long before the crisis the need for intervention existed and the height of our art consists in its timely recognition.

The physiological principles of treatment.—Among the therapeutic agencies suggested by physiology some of the most important are: rest and sleep, activity and energy, habit and change, and physiological rest.

Rest and sleep.—No amount of simple rest of the body can do duty for sleep. Though mere repose may partly satisfy the needs of our vegetative life, sleep alone, that profound sleep which the poet has likened to death, can make good the wear and tear of the higher nervous centres. The difference between individuals in all that relates to sleep is remarkable and would well repay systematic study. Whilst a minimum of sleep is requisite for all there are great varieties as regards the duration and the quality of sleep, and in all of us these are greatly influenced by habit and education. It is the privilege of some to command sleep at any moment, but it is probably exceptional to combine this facility with that of remaining awake at will—a dangerous power when it is abused. Some possess the opposite peculiarity and are subject to the invincible desire for sleep after a definite expenditure of nerve energy. By this they are protected against exhaustion. Interesting physiological speculations, and some practical notions also, are suggested by the remarkable relief and freshness which they derive from even a very short period of sleep. Much tissue repair cannot have taken place during those few minutes of profound sleep which will restore a jaded man to full activity. The energy which he subsequently develops must have been there when he fell asleep, yet it was unavailable. It is therefore clear that these brief and irresistible slumbers are essentially different from the long sleep of the night and that we might turn both the short and the long sleep to separate therapeutic account.

The therapeutic value of sleep and of hypnotics.—Hypnotism, in the sense of a systematic method of animal fascination, does not form part of the present subject. Although it has been given an extensive trial by French neurologists it has never found much favour with us. In some of its applications, though not in all of them, it is one of those extra-physiological, not to say anti-physiological, methods which seek delusive results by fostering a weakness which it should be our duty to combat. Legitimate sleep which strengthens volition together with the rest of our faculties has not yet received the full amount of study which it deserves. Our practical knowledge of the relative value of our many hypnotics is also in a rudimentary stage. In the waking state the effect taken by our various drugs upon the nervous system is manifestly different. Similar differences may obtain during sleep between the actions of the various hypnotics. The sleep which they severally procure is probably not, as we may have assumed, an identical quantity. Differences in its duration and in the varying delay of its onset must have struck the least observant; but its quality must vary quite as much as we find it varying in the absence of any drugs.

The various degrees of sleep as they range from coma, where both the nerve cells and the conducting fibres are absolutely impervious, to the light sleep of those whose irritable and quick nerve protoplasm is immediately thrown by the touch of a feather or by the slightest sound into that state which means open conduction and full consciousness, there is every shade of quality. The disordered cerebration of delirium and of dreams almost suggest a possibility that orderly communications may pass between local groups of cells, and this might perhaps explain the good counsel which is bred of the night. But these incubations would be merely local settlings of the balance of the day between cells disciplined to collaboration and would be during sound sleep incapable of a wide diffusion throughout the mental sphere.

Long sleeps and short sleeps.—Sleep then would seem to have two offices, both fulfilled in the long sleep of the night which it is our usual endeavour to secure for our patients—

Digitized by Google

viz., that of favouring the slow anabolic changes of repair and that of interrupting consciousness by uncoupling the chain of neurons or conceivably by relaxing protoplasmic tension or tone. This relief of tension is it would seem the only office performed by the shorter spells of sleep and therefore the two forms of sleep suggest two therapeutic objects.

The night's sleep may come without any drugs, but it might need even then to be bettered, and in improving the quality of spontaneous sleep our help is often of value. It might also need to be prolonged.

The systematic prolongation of sleep for the cure of disease is one of our opportunities hitherto little used. In chorea sleep entirely subdues the muscular agitation and this observation has led to the attempt to arrest the disease by prolonging the sleep for considerable periods. A complication arises in connexion with alimentation which in this disease, as in most other nervous troubles, is of primary importance. Partly for this reason, and because more than rest may be needed for a cure, the results hitherto reported have not sufficiently recommended the method. Prolonged narcosis has also been suggested on the principle of physiological rest in excessive wear and tear of the nervous system. In various nervous affections, including the mental, its renewed trial, combined with suitable methods of feeding, might lead to encouraging results. Better suited perhaps to our every-day needs is a systematic resort to the *shorter sleep*. Like the light instalments of food which restore the lost function of appetite and digestion, short sleep in the day may be essential to the cure of nocturnal insomnia. Our growing wealth in hypnotics warrants a hope that a suitable agent may yet be found which in that direction would minister to the health of the invalid and might command the luxury of sleep at any opportune time for the convenience of the worker.

Body rest as a systematic therapeutic agent has long found its place in our modern treatment for patients whom weakness alone, in the absence of medical advice, would not have compelled to take to their bed. To that class belong the frail women in whom the debility of anæmia, of dyspepsia, and of over-fatigue develops symptoms often mistaken for hysteria. Rest in bed is their first need. In the treatment of chlorosis this is now recognised as the essential element for a rapid recovery. Again, its methodical employment forms an essential part of the Weir-Mitchell plan, but its most striking instance is that of the open-air rest cure for phthisis which within quite recent years has largely replaced at foreign sanatoria the previous method by muscular exercise. The pendulum of medical opinion has swung towards the principle of physiological rest and it is claimed with much reason for this plan, which is combined with liberal alimentation, that rest is essential to the cure of the pulmonary lesions and does good by allaying the characteristic irritability so well displayed in the pyrexia occasioned by exercise or excitement. The prolongation of rest for the muscles over extensive periods cannot fail to occasion some atrophy of the muscular system and of the heart itself. This consideration has led to the mitigation of the rest cure both as regards its duration and its absolute character, and in suitable cases graduated exercise both passive and active and other hygienic methods have been adopted as part of this treatment in its most recent developments.

PHYSIOLOGICAL REST TO THE ORGANS—ABSOLUTE AND RELATIVE.

The efficacy of rest, so ably set forth from a surgical standpoint by John Hilton in his lectures on Rest and Pain (1861-62) as part of our natural therapeutics, has now obtained full recognition in connexion with the organic functions. Its principles are applicable to them. Rest which in the vegetable kingdom is a condition of growth and of repair is a still more prominent factor in the daily visceral life of animals.

Absolute physiological rest to organs is sometimes provided by modern surgery, as in the case of the larynx in tracheotomy, of the rectum in colotomy, of the œsophagus in gastrostomy, and of the pylorus in gastro-jejunostomy. In medical treatment the same principle has received free acceptance, but there has been little scope for its use which has remained almost restricted to the nervous, the muscular, and the alimentary systems.

Rest to the stomach.—Absolute physiological rest of one of our organs can only be secured by deeply interfering with another, sometimes to the extent of reversing its functions. The most striking instance in point is that of the complete suspension of gastric alimentation with the help of rectal feeding. So far as it secures physiological rest to the stomach the result is satisfactory, but at first sight the method is unphysiological. We turn the rectum, an excretory organ, into a channel for absorption. A similar readjustment and reversal of functions is sometimes seen in disease as in the case of the lymphatic system. When the kidney refuses service the function of absorption peculiar to the lymphatics is apt to be reversed. The lymphatic system may then become a reservoir and ultimately, if ulceration of the skin should occur, a channel of excretion for superfluous fluid and for the solids dissolved in it. These facts carry suggestions which some day may be more widely utilised.

Partial physiological rest is much more easily applied in medical treatment and we spend our lives preaching the lesson of moderation, but specially in the direction of the nervous and of the alimentary system. It is perhaps a redeeming feature of illness in general, but more particularly of enteric fever, when it strikes down the middle-aged man that it affords his overworked nervous system a prolonged and timely rest. If the renovation of tissues which is one of the results of a consuming fever were an unqualified advantage, then the Lenten fast and the more extraordinary fasts of certain professionals might claim some foundation in science. More probably, however, the favourable result which is often observed in the convalescent from typhoid fever is the effect of the prolonged rest of many functions, including those of the stomach and of the liver, but more especially of the nervous system. When convalescence is happily conducted the sufferer may find himself a new man, disencumbered and refreshed, with a more active stream of nutrition which reminds him of younger days. But we need no lesson from illness. Our treatment of the nervous system by rest is sufficiently confirmed by its results. Again, in connexion with the alimentary system the advantages of partial rest are evident as in that wholesome cure for the prevalent results of abuse of food as a mere stimulant—an exclusive milk diet combined with rest in bed. Who has not been struck with the singular contrast between the frugal diet, often small in bulk, of hard-working labourers and the weight and superfluous richness of that of the unemployed? With the latter the labour is visceral and the penalty as well, and their life is mainly shortened by this organic overwork of stomach, liver, and kidney. In vain has modern fashion endeavoured to lengthen the intervals between meals by deferring the midday feast and throwing back the late dinner nearly to the hour which summoned our forefathers to bed. An additional afternoon meal has crept in between them and the early cup of tea before rising also belongs nowadays to elementary hospitality. The least the stomach can claim is that its digestions should not overlap. Unfortunately even its single opportunity, the long rest of the night, is too often encroached upon and a meal of indigestibles thrown in at 12 or 1. Half this amount of food would keep a man in strong work; the idle, even if they be strong, must break down under its weight. Alone the dyspeptic is safe whose constitutional weakness acts as a merciful protection. Physiological rest in this direction is much needed.

HABIT AND CHANGE.

The same principle lies at the root of these opposite agencies. Habit and change are both conservative and their influence in saving energy is most marked in connexion with the nervous and the alimentary system.

Change of scene, change of rest, and change of occupation are all beneficial for the nervous; but it is neither the scene nor the rest nor the work, but the change that does most good. Most often the machine is suffering rather than the energy and it suffers in those parts which have long borne the same recurring strain. Let other cerebral districts be laid under contribution and the overworked areas will obtain their physiological rest. Work in this way becomes productive of rest. Greater still is the relief when mental occupation is exchanged for that which is purely mechanical, and this is part of the secret of the relief to brain fatigue conferred by muscular exercise, which also alters the rate and quality of the metabolism. In the alimentary system analogous benefits are derived from change and the same is also true of our medicines, which it may be wise to alter for the sake of variety and in the hope that a return to the original prescription may be followed by a renewal of its original benefits.

Digitized by Google

Habit differs from change in the field of its usefulness, but is not far behind it in economising fatigue and in sparing effort. The value of habit lies in the easier performance of those things which are in themselves healthful, whilst change is sovereign in breaking a deleterious succession. Regularity of life and much abused routine will long resist the wearing effect of time and to the well-rooted habit of living many a veteran has owed his ample years.

The cultivation of habit as influencing nutrition.—Habit is intimately connected with rhythm and with the establishment of paths of lessened resistance by constant repetition. It has been alleged that since function is after all the concerted action of many individual cells the education of habit might be regarded as the education of the cells themselves and that we might thus trace its existence and development down the scale of functions, of organs and of tissues, to the cells as a determining influence in their growth and characters. Without holding opinions so advanced we perceive in the vaso-motor system and in its reactions endless instances of the influence of habit upon functions and of the reaction of rhythmic functions upon cells. Leaving aside all theory we may award a place among our modern principles of treatment to the cultivation of habit as a means of influencing intimate nutrition. To put the matter in a more concrete form a life without effort or excitement would do little towards educating any higher habit but would tend towards disuse of function and degeneracy of cells, whilst sufficient training both of the mental and of the muscular activities, to say nothing of the visceral, would be capable of educating certain attitudes of the vessels and of the tissues which they feed and of keeping up above all the habit of muscular and elastic response. This question verges dangerously upon the vexed limits between physiology and pathology. Atheroma has been generally attributed to overwork and overstrain. I have never been able to satisfy myself that this is in every point a rational explanation; at any rate, relative defect or stagnation of nutrition and abeyance of function appear to be dangers not less real which may threaten the vitality of the vessel wall.

FUNCTIONAL ACTIVITY AS A PHYSIOLOGICAL PRINCIPLE OF TREATMENT.

Atony, delayed nutrition, and atrophy are the dangers of rest. Activity and function are the chief stimulants of nutrition. The tendency of properly regulated activity is to strengthen function just as it tends to hypertrophy the tissues. Both muscle and nerve and the body at large are "toned up" by activity and their nutrition is increased. In this total effect there is a reciprocity between the periphery and the centre. Powerful innervation favours the peripheral mechanisms, but we cannot doubt that the nerve centres derive assistance from the work and the tone at the periphery. Upon this principle may be founded a systematic education of the brain by the education of the peripheral mechanisms and particularly of the hand. This principle has considerable application in the treatment of backward children and in many others whose aptitude is at first rather mechanical than towards the abstract. Conversely, we have abundant instances of a central education of muscle in the marvellous dexterity attained in various arts. Concentration of thought and mental effort upon the contracting muscles, as in the modern training of athletes, is also an instance in point. The bringing into play of the function which has been rested is the most important part of the treatment by rest. Passive and active movement and graduated muscular effort are now resorted to in the treatment of a variety of conditions. Many sufferers, particularly those affected with chronic disease, are treated largely out of bed who were formerly confined to absolute inertia. The healthy heart itself is our best exponent of the great principles of rest and activity. In health cardiac rest is actually apportioned to cardiac work. In the treatment of cardiac disease the share of rest is a very large one and until recent times it was almost an exclusive share, but our principles have undergone considerable alteration. Whilst in phthisis the latest endeavour has been to keep the lungs at rest the prevailing tendency of cardiac treatment is now to gradually train the heart for action. The modern methods identified with the names of Oertel and of Schott are so well known to you that their mention will suffice.

THE RESERVES OF FUNCTION AND THE PRODUCTION OF ENERGY.

Towards the fatal termination of chronic disease our remedies are in vain. For a long time waste has been in excess of repair until at last the function of the higher organs ceases from want of a sufficient supply of force from the exhausted cells whence it should arise. In acute disease the issue of the struggle for life depends upon the amount of work still to be got from the vital organs in spite of the exhaustion which their cells may already have suffered. Organs which prior to its onset were only just equal to the demands of healthy life would break down for want of any available reserve of power. Energy in a general sense is the relative organic capacity for supplying force, and this supply may, as suggested, be inferior, equal, or superior to any special requirement. It may now be stated with less risk of misunderstanding that our first therapeutic desideratum in resisting disease is a margin or reserve of energy. Much energy is latent and may require some extraordinary stimulus to bring it into action. We are all familiar with the surprising amount of muscular work obtained in excess of that which ordinary volition will command under the influence of anger, alarm, or suggestion, even in those who are habitually torpid. In the "energetic" the capacity for work and its actual amount are manifest and this brings out the particular meaning of the word "energy" as used in current language. It is the capacity for work of the nervous system in its office of animating the entire assemblage of functions, organs, and cells. Inasmuch as it raises the energy and calls forth the work of the several organs, energy, understood in this limited sense, is itself a function and as such capable of education. That which is true of this central and ubiquitous function is equally true of the organs, each of which can be trained by special attention and acquires thereby that structural increase which is the basis of energy and the storehouse of force. Likewise we cannot doubt that hypertrophy and strength of the nervous elements must be the result of their constant use.

The question "Can energy be manufactured?" is therefore perhaps not so absurd as it may sound at first. The feeble primordial cell contains little more than the vitality of the future Cæsar—all the rest is imported. Food will bring the stuff upon which energy will grow, and yet how easily under unsuitable circumstances may food itself extinguish it. The growth of energy during the development of the organism may be raised or depressed in the measure as function is promoted or prevented. Its originally rich promise will avail nothing if its development be arrested by disuse. And its neglect or cultivation will react upon vitality itself and longevity. The growth of effective energy might be regarded as proportionate to the abundance and to the degree of the various organic activities set up between functions—in other words, their mutual stimulations. And if this be correct a judicious training of organs is essential. Active workers, whether with muscle or brain, are aware of the vitalising effect of habitual activity. In conclusion, it would appear that whilst the energy of the organs and of the organism may be suppressed it may be systematically raised, and this is our practical function against the chances of future disease, when the reserve of organic energy is to be the deciding point. Considerable inequalities under similar environment are observed between individuals even as regards the facility for production of the energising stimulations to which reference has been made. In some, apparently deficient in energy, a suitable change in the circumstances or environment may bring into play the increased scale of stimulation which the ordinary environment in the case of that individual had failed to afford. Instances of this apparent manufacture of energy by function is afforded by the special education of imperfect intellects, as at Earlswood—by the gradual vitalising process applied to torpid subjects—and by the more difficult treatment of neurasthenia.

PHYSICAL EDUCATION FOR MEN AND WOMEN.

A great outcry has arisen of late against the excessive importance attached to athletics at schools, at the universities, and at our medical schools, and in the columns of the daily press. The facts may partially justify the criticism. Perhaps a less severe view might be taken of the matter. In this age of unrest and of nervous strain there is little prospect of any slackening of the speed. Some of the consequences of this excessive nervous expenditure have already been noted—neurasthenic affections, insanity, general paralysis, premature senility, and a diminished birth-rate are partly attributable to this cause. The best corrective is probably a more general adoption of muscular exercise as part of our daily life. Muscular exercise, it is alleged, delays the

Digitized by Google

passing of examinations, not only by consuming time, but by dulling the brain. For my part I would not discourage athleticism in our pupils, for we are all familiar with the excellent results arising from a happy combination of sport and study.

Men in this country have always been athletes and sportsmen. There is, however, something new and to be watched with interest in the spreading cultivation of physical exercise by women. The female world has perhaps never been so much addicted to athletics as in the present day. It has been reserved for our own time to extend to a larger circle sports and games which are the more healthy because enjoyed in the open air. Croquet, lawn tennis, golf, and the bicycle have been the progressive stages through which this development has passed. Among these pursuits the bicycle has done more than any other to revolutionise the formerly so carefully measured tenor of feminine existence, and coming into favour in the declining years of the century it has by some been held responsible for some of its many changes. So considerable a revolution cannot be left unnoticed in its medical aspects. The first outcry against its alleged detriments is already subsiding and even specialists have not condemned it. Muscular exercise is a cure for nerve overstrain and irritation and we can point to its favourable results. Young women are growing up to a greater stature and weight, with better complexions and healthier nerves, than had been witnessed before. These considerations open a wide subject. The health of the people is of no less moment and for them little has hitherto been done. If the improvement to which I have referred is not an imaginary one it should be shared by the millions. One of our most urgent duties will be the provision for the poorer girls of adequate means of healthy exercise. Hard work they get in our great towns, but exhilarating exercise is unknown to them. A praiseworthy movement has been set on foot under the presidency of the Earl of Meath and a British college of physical education was founded in 1891 and incorporated in 1897. This may become the nucleus of a widespread movement which might end in branches being attached to every school in the country.

THE PUBLIC AND THE PROFESSION.

I have anticipated in my first lecture some of the remarks which belong to this part of my subject and I have hinted at the increasing curiosity of the public in matters medical. In some ways the public is more exacting than it was. This is largely due to the increased publicity of information which was formerly regarded as strictly professional. One result is that an opinion is demanded in many cases where it would be wise to keep the diagnosis from the patient. But there is a growing difficulty arising from the modern facilities for communication by the post, by the telegraph, and by the telephone. Although so much versed in medical affairs, in one particular the laity are not sufficiently informed as to their working. Patients do not always realise that letters can kill. Advice and explanation are easily asked for. It does not strike the inquirer that for two minutes spent over such a message he expects the sacrifice of much time and labour from an overworked man who, let alone any much-needed relaxation, has not time for some of the most urgent requirements and the assumption by him of the anxious responsibility of hurried writings which nothing would tempt him voluntarily to undertake. It were well if the public were enlightened in this matter.

Treatment without advice and advice without treatment.—I need not refer to the number of periodicals addressed to the public, and particularly to the masses, in which professional matters are discussed and professional advice is offered by the editor or his correspondents. In this way many to their detriment resort to treatment without professional advice and the various consequences to which this leads are well known. They affect the practice of medicine and the practitioner. His opinion is not always regarded as the last word on the subject but the patient's and friends' first impulse is often to question it and to seek further advice. And thus the patient is becoming an unstable entity, more owing to our *fin-de-siècle* restlessness than to any blame attached to the medical attendant. The medical attendant himself is much discussed, but the criticism of treatment is a more serious matter because it affects the patient's interest. Some patients discuss it with their friends. Others are more inclined to read the most recent books on the subject and frequently are depressed and made worse by their efforts. Systematic serial consultations are one of the results based upon the deep-rooted conviction that medical men differ. This leads to much practice and is the chief column of support for the consulting fraternity. The consequence of this is that many go from one authority to another getting excellent advice; but the treatment cannot be established on any firm or consistent basis and but few of the things recommended are ultimately carried out. This is the other evil—that of advice without treatment.

ABSTRACT OF

The Morison Lectures

ON

THE RELATION OF THE NERVOUS SYSTEM TO DISEASE AND DISORDER IN THE VISCERA.

Delivered before the Royal College of Physicians of Edinburgh on Nov. 7th, 9th, and 11th, 1898,

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,

PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL AND CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

LECTURE II.[1]

Delivered on Nov. 9th.

DISORDERS OF VISCERAL SENSIBILITY.

SIR JOHN TUKE AND FELLOWS,—It may be remembered that when discussing some points in the physiology of the visceral nervous system last year I drew a parallel between viscero-motor actions in general and cardio-motor action in particular, arguing that while the products of such motions differed with the organs which were the seat of motion the mechanism of such action, whether anabolic or katabolic, was essentially the same. It is possible in Protean nature to push a parallel too far and I have no desire to become too general in discussion. But it appears to me that it will be convenient in considering the relation of the nervous system to disease and disorder in the viscera to divide these into two large categories—namely, into disorders of sensibility or sensation and into disorders of motility or motion. The brain could no doubt be thus considered collectively with the other viscera, but there is a certain difference between the former and the latter which, together with the special character of this lectureship, renders it desirable that that viscus should receive separate treatment. There is, indeed, throughout the body, as there is in every organ, a functional unity which might be more accurately termed a tri-unity due to the consentaneous operation for the production of a common result of the peripheral organic cell, whether in brain or muscle, a central regulating cell and its nerve channels, and the bond of union between the two—namely, the blood with its stimulating and life-giving properties. Recent physiological thought appears rather to have dissociated this essential unity and much ingenuity has been exerted to show how very well the organs can get on without the nervous system. The question of non-neural cardiac rhythmicality was touched upon last year and I traced the controversy from the now untenable assertion of an absence of nerves in general in the cardiac apex to that of an absence of ganglion cells in particular in that portion of the organ. Personally, I endorse Henry J. Berkley's physiological standpoint, although I cannot agree with his description of the cardiac ganglion. His words are, "Cajal in portraying the Auerbach plexus by the vital blue method gives a picture that is not entirely dissimilar to our cardiac nerve plexus with the neural enlargements and nerve-cells, though in the cardiac plexus the nerve cells are vastly inferior in number, different in appearance, and do not occur in clusters; yet the general likeness is sufficient to allow of some comparison being drawn between the two."[2] This is fairly correct as regards

[1] Lecture I. was published in THE LANCET of Dec. 17th, 1898.

[2] The Johns Hopkins Hospital Reports, 1894, p. 89.

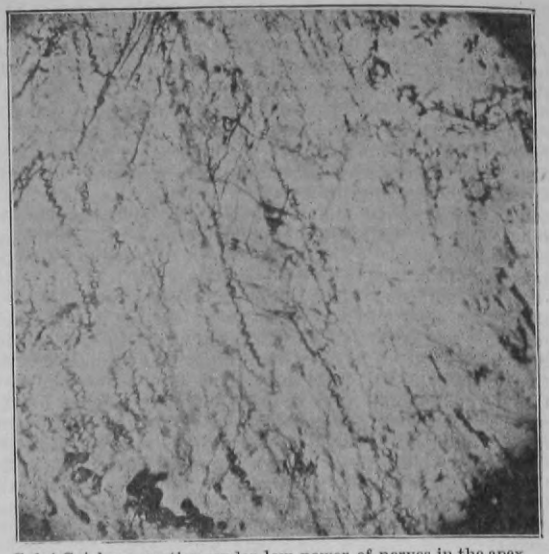
Digitized by Google

the lower third of the heart which Berkley examined and I shall show some of those ganglia of the apex which agree in great measure with this description. But in applying his words to cardiac ganglia generally Berkley's description does not apply. As I demonstrated last year the cardiac ganglia of the vagal system, as I take them to be, may consist of very large clusters of cells such as the fine specimen I now show on the screen and which was figured in THE LANCET and *Edinburgh Medical Journal* for 1898. My reason for regarding such ganglia as pertaining to the vagal system is that they bear much the same relation to the peripheral distribution of the nerve that the plexiform ganglion does to it at its origin and they are to be met with in many of the organs to which the vagus is distributed. The important point, however, is that, character apart, the apex of the heart although not profusely is nevertheless sufficiently ganglionated and the Hallerist must look for some other support than his anatomical argument. Physiology affords more scope to the imagination. But we saw that the presence or absence of ganglionic cells was after all a matter of small moment to the Hallerist. They were nutrient or something else. In any case they had little to do with motion in any organ. You cut a vagus and the heart does not feel it long. You detach an organ and stimulate it and the functional result is there. It has been shown, however, that if you cut both vagi the staying power of the heart is seriously compromised. Balint has shown that if aortic regurgitation be artificially established and one vagus cut the action of the heart is not materially interfered with—the compensated organ continues to act efficiently—but that if both vagi be divided the heart, even although it has undergone compensatory hypertrophy, soon gives out and the animal dies in about a week with well-marked evidences of retrograde stasis. Survival after the division of one nerve is probably the result of what may be termed incomplete peripheral decussation in the organic plexus—a subject, as it appears to me, of much practical interest and one which I have examined somewhat, but my results are still too rudimentary for publication. The nerve from one side probably sends fibres to both sides in such unified organs as the heart, while division of both nerves naturally destroys such a nerve-supply and saps the fountains of persistent rhythmicality.

Inasmuch, however, as anatomy lies at the foundation of our knowledge of all forms of organic activity it would have been a difficult matter for the adherents of a neural theory of sustained motion to have defended their position had it been possible to point indubitably to mobile structure which continued efficiently to act for a lifetime without such endowment. The conception of such a condition would *a priori* seem unreasonable, but as the unexpected does occasionally happen it was just possible that such a fact might conveniently come to the aid of the distressed Hallerist. This was supposed to be so in the case of the intracranial vessels. Some of the peculiarities of the intracranial circulation certainly appear at first blush to lend probability to the occurrence of an exceptional condition in this sphere. The resistant skull-cap, Alexander Monro the second's suggestion of the full bottle held upside down without spilling its contents, Kellie's well-known experiments, and much argument founded thereon suggested that vasomotor nerves had little to do with the intracranial circulation. Some, like Hill and Bayliss,[3] argued that nerves were absent because they had not been found and for the purposes of their theory it was necessary to assume such absence. In my ignorance I had assumed that these vessels were innervated until Sir John Tuke informed me last year that they were supposed not to be. Were this so, I felt that I was standing upon somewhat thin ice in much that I had to say and I found it advisable to walk somewhat a-tiptoe until I felt more secure. I therefore determined to investigate the point at an early stage of animal life when the tissues appear to be, as a rule, most amenable to staining methods. As I have related in the *Edinburgh Medical Journal* for November of this year, I selected the fully grown fœtus of a cat for the purpose and was fortunate enough to find not only that the pial vessels were fully innervated by an ample plexus, but also that branches of nerve might be found in close relation to blood-vessels which bore fully developed and permanent ganglion cells. Thus, then, another non-neural persistent rhythmicality has found its way to the limbo of many an ingenious hypothesis. The preparations under the microscope and their reproductions on the screen show these structures the relation of which to sleep and cerebral activity must be a very important one. Assuming, therefore, that the nervous system bears an important relation to splanchnic as well as somatic motion in health, I assume also that that relation is quite as important in the case of disordered visceral sensibility and motion. Having argued that motion, whether sensory or mobile, to use a convenient although tautological expression, is one in kind in all organs although modified by the functional nature of the organ manifesting it, I shall take as the type of disordered sensibility and motion abnormal conditions of the heart for fuller discussion, as those with which circumstances have rendered me most familiar and shall apply the lessons which they seem to point as rationally as I can to disordered sensibility and motion in other organs.

On the threshold of such a discussion it seems necessary to inquire what the local elements in visceral or referred pain are? It occurred to me that the uterus might be taken as the best physiological type of visceral pain and that an examination of the finer innervation of that organ might throw some light upon the general question. This I have accordingly done and should I in the course of my anatomical remarks relate facts known to others and discovered by others without due acknowledgment I must plead ignorance of such previous work and can therefore disavow any intentional plagiarism. A lateral branch from a large nerve in the uterus is given off so that the portions chiefly constituting it appear to run in opposite directions in the outer strands of the parent nerve and within its adventitious sheath. Fibres may also cross over the trunk from the opposite side to join the branch. As the branch increases its distance from the main stem its division for distribution takes place as one would expect by gradual subdivisions which naturally diminish the size of the parent branch. On examining the mode of distribution of a small branch or twig and noting its relation to blood-vessels we find that some of the smaller sub-divisions tend to follow the course of the vessel and others cross it for final distribution to individual muscle fibres. The branches following the vessels form a plexus around them, a sort of plexal tube or sheath through which the vessel runs, and by twigs from which it is innervated. Before distribution to the organic muscle triradiate nuclear points of dispersion may be observed as in other structures, such as the pial membrane and the pelvis of the kidney. Nuclei strengthening fine fibrils may be observed in the uterus as elsewhere, but I have also noticed a peculiar relation of some neural swellings or nuclear points on the uterine fibrils which I have not seen elsewhere but which may nevertheless quite possibly occur. A rounded nucleus may be placed quite laterally to the fibril so as to constitute a rounded knot or excrescence upon it, and which is so rounded and displaced laterally as to convey at first sight the idea of a small ganglionic cell but which on examination by high power ($\frac{1}{12}$ immersion) reveals nothing more than an irregularly stained nuclear body somewhat resembling a small Paccinian corpuscle but without the characteristic striation of the latter. The local causes of pain in the parturient organ which may for convenience be termed visceral pain are uterine and extra uterine. By extra-uterine pain I mean such as is caused by pressure upon surrounding textures, including those innervated by purely somatic nerves as the uterine contents are extruded. With such pain I am not at present concerned, although it perhaps constitutes a great, if not the greater, portion of the pain incidental to labour taken as a whole. The total pain is, however, undoubtedly commensurate with the degree of uterine contraction and some of it appears to be localisable in the uterus itself, for pain is present before extra-uterine pressure is a considerable factor in the situation and also after labour is over, when coagulated blood or other residuum has to be extruded. Such essentially uterine or visceral referred pain must, it appears to me, be caused by intramural pressure upon sensory nerve structures distributed to the muscle. The absence, however, of visceral pain under circumstances in which we might *a priori* expect it to be present is a striking clinical fact. As we saw last year the visceral nerves in the absence of inflammatory states are so little sensitive that organs may be freely manipulated and even injured without the evident production of painful sensation. Nodules of malignant disease may also stud a viscus and cause little pain. Cysts may rupture into the pericardium and elsewhere, causing death, of the presence of which there was no sensory or other evidence during life. On the

[3] Journal of Physiology, 1895.



Digitized by Google

other hand, it is commonly observed that in certain situations and without inflammatory lesion visceral pain may be as well marked in the splanchnic as in the somatic nervous system. Large calculi may lie in a gall-bladder for a lifetime without causing pain, but even a small one under the peristaltic grip of the bile-duct may cause an agony which from its very intensity may prove fatal. The same is true of renal calculus. The stone once engaged in the ureter may jeopardise life and even cause death from collapse due to the severity of pain, while very little and it may be no pain may attend its presence in the pelvis of the kidney which we have seen is richly endowed with nerves having the anatomical character of peripheral sensory nerves. Slight causes may, moreover, provoke great visceral pain, such as the colic which is due to very moderately irritating material in the alimentary canal.

It would appear, therefore, that visceral pain in the absence of inflammatory conditions may be of direct and indirect origin and that it has some relation to the degree of pressure exercised upon sensory nerve endings either directly by such action as the passage of a calculus through a narrow peristaltic tube or the indirect spasm induced, it may be, by slight causes in the visceral muscle. It is, therefore, the implication in disease of orifices having contractile cavities behind them which is most calculated to make pain a prominent feature in clinical histories. Thus the strictly local ravages of disease in a viscus may be painless, but the provocation by it of tetanic muscular action or cumulative peripheral pressure may cause much suffering. Finally, visceral pain may be the peripheral expression of a central lesion. That pain should be referred to a locality where the original stimulus is situated, as it must of necessity be somewhere, does not seem in any way remarkable. It is but a form of touch, a painful touch, and the whole utility of touch, whether painful or otherwise, is to indicate locality and the character of the circumstances surrounding a sentient being. Pain may, indeed, in some measure be regarded as a beneficial provision for the preservation of the individual. But the experience of pain not at the site of its cause is somewhat remarkable. The surgeon is familiar with the pain of vesical calculus referred to the end of the penis and with the knee pain of hip-joint disease. In like manner do the visceral crises of tabes appear to be caused by a peripheral projection of sensory irritation from structures in process of sclerosis.

With this introduction I pass to the consideration of cardiac pain as a type of disordered visceral sensibility. The natural provision made for safeguarding from undue mechanical stimulation the nerves entering and permeating an organ is nowhere better seen than in the heart. If the heart of an animal be taken which has died in systole and be fixed in that tetanic state forthwith by being placed in alcohol, microscopic sections show well the means adopted by nature to protect both vessels and nerves from undue squeezing by the close-grained organ. The specimen I throw upon the screen is from the apex of a sheep's heart prepared in the manner stated. The largest nerves may be seen to be situated nearer the vein than the artery, as they enter the organ at its surface, while the neuro-vascular atrium is also well padded with fat. The whole constitutes a perfect contrivance for obviating undue pressure from the surrounding muscle which may be observed to be in a state of systolic contraction. The same perfect adaptation to circumstances which we see at the surface obtains as we follow the nerve trunks into the organ, the vessels and nerves coursing largely together and being protected in more open situations by associated fat cells. The heart being like the uterus, an organ having a wide range of contractile variability, if the suggestion I have made in explanation of the tortuosity of the uterine nerves hold good we should expect a somewhat similar provision to exist in the heart also, and we find that it is so. Coils such as are met with in the uterus are not found for sufficient reasons which need not be discussed further than by pointing out that the return of the organ to smaller size is but momentary in the case of the heart and the difference between its maximum and minimum less than in the case of the uterus. Berkley[4] refers to the "wavy" nature of the nerves passing through the cardiac muscle. My preparations like his were made from the lower third of the ventricle and include of course the absolute apex. The rich innervation of the part is well seen in the specimens I place under the microscope which I stained by the quick Golgi-Cajal method and also from their reproductions on the screen. It will be observed that waviness is a very mild term to express the almost corkscrew tortuosity of some of the nerve trunks depicted. One can readily conceive the perfect

FIG. 1.

Golgi-Cajal preparation under low power of nerves in the apex of a cat's heart showing their tortuosity.

adaptation of such a contrivance for suiting the altering state of the organ in systole and diastole. In the systolic organ as in the non-gravid uterus the threads of the screw, so to speak, are approximated, while in the diastolic organ as in the gravid uterus they are extended. Now, dilatation of

FIG. 2.

Golgi-Cajal preparation of nerves in the cardiac apex of a cat. G marks a ganglion.

the heart is in a sense a partial and persistent diastole, a condition in which the threads of the neural screw must be somewhat extended and it is conceivable that such extension may be associated with a degree of sensory stimulation having in its train various degrees of motor consequence to which reference will be made in their proper place. At present we are concerned with sensory phenomena and we know that the sensory incentive to motion—a reflex—need not be experienced as a sensation unless the resultant motion be of a type to induce sufficient peripheral stimulation to cause pain. This, I believe, it may do. Then one of the forms, the indirect form, of angina pectoris is the result. Stimulation of the cardiac nerves on this principle, which is

[4] Loc. cit.

Digitized by Google

not provocative of visceral spasm may cause various irregularities of rhythm to which also I shall refer later, as well as various degrees of sensory discomfort not amounting to angina which cardiac patients frequently experience.

We have seen that the cardiac nerves in penetrating this organ are more or less intimately associated with blood-vessels and in the case of the larger vessels this association may be seen very distinctly in some of the specimens I show under the microscope and on the screen. The nerves in fact on transverse section may be seen to crown the arteries as the arteries themselves crown the heart. On longitudinal section they may be seen to course with and around the vessels. We can understand, under the circumstances, in the event of a hardening and irregularity of the arteries such as we meet with in advanced stages of arterio-sclerosis with calcareous degeneration, when associated, as it frequently is, with a cognate change in the interstitial tissues of the organ and in the interspaces along which the vessels and nerves find their way, how actual frictional contact with irritation of nerve trunks may induce frequent and ultimately fatal attacks of cardiac pain. Angina pectoris thus originated may be regarded as the direct type of angina or visceral pain, like the pain caused by the passage of a calculus along the bile or urinary ducts. It has been cogently objected to this theory of angina pectoris, that were it true, angina should be more constantly associated with the conditions mentioned than it is found to be. Atheromatous arteries are frequently met with after death which do not appear during life to have caused cardiac pain. I trust I may not be thought to assume too dogmatic a tone in the presence of some whom I regard as the chief authorities upon the subject which I am discussing when I express my belief that the association of angina with calcareous degeneration of the coronary arteries and hyperplasia of interstitial cardiac tissue is dependent in a great measure upon the degree of change in the vessels and in the channels in which they run, associated it may be in some cases with a certain amount of visceral neuritis which as we know would be calculated greatly to increase the sensibility of the nerves involved.

There are those who have described an anatomical sensitisation of the endocardium, and if they be correct, it is conceivable that the incentive to angina from increased blood-pressure within the chambers of the heart may be due to stimulation of such endocardial innervation. Professor Clifford Allbutt also ascribes great influence to intra-aortic tension as an etiological factor in angina pectoris. For myself, however, I am more disposed to regard intramural and intra-aortic stimulation of nerves as the cause of those reflex muscular changes which induce visceral pain, just as I attribute to similar causes the essentially visceral pains associated with a uterus in rhythmical action of a certain intensity. Such conditions as favour adynamic dilatability of the chambers of the heart, whether from local disease or general debility, are calculated to induce such stimulation and reaction as I have referred to and are most calculated to result in angina when to the indirect influences I have mentioned there are added local causes of intramural stimulation of the cardiac nerves.

Painful affections of the heart may as is well known be associated with somatic points, areas, and radiations of pain, and Walshe has described the opposite process of peripheral aura resulting in central cardiac distress.[5] In the case which Walshe refers to the pain began in the hand and spread up the arm to the chest. This must, of course, merely be regarded as the peripheral projection of a central stimulation, such as the shoulder pain associated with some hepatic conditions and other well-known somatic manifestations of visceral stimulation. For the local origin of angina is to my mind indubitable, and this conclusion has been impressed upon me by the situation in the right arm of anginoid pain in a rare case of dextral valvular disease of the heart which I published in the Transactions of the Pathological Society of London in 1876.

It does not follow, however, that cardiac pain may not have a truly extra-cardiac origin. Less frequently than in the case of some of the other viscera the painful crises of dorsal tabes may affect the region of the heart, as is stated by von Leyden and Goldscheider,[6] who quote other authorities for the same fact. The attacks may have the severity of *angina vera* and even threaten life. Whether the sensory phenomena of such crises may originate as some have supposed in the pneumogastric system may be left an open question. That the pneumogastric does not play the important part in the painful symptoms of visceral crises which was at one time assigned to it is fairly certain in view of our present knowledge of the pathology of the disease. In some cases, however, there appear to be grounds for associating such cases with central pneumogastric irritation, for although the nerve has a largely trophic influence its spinal sensory fibres, coming as they do from the far-reaching solitary fascicular strand, may be regarded as quite as efficient channels for sensibility as the lower spinal nerves and posterior root ganglion. All the phenomena of sensory localisation and radiation, however, in cases of visceral angina, whether cardiac, hepatic, or renal, indicate the spinal rather than the cranial nerve-supply as the chief territory of objective pain. This point would appear to have been first emphasised by Dr. Allen Sturge.[7] Ross[8] appears to have come to the same conclusion independently. Professor Clifford Allbutt made a similar suggestion in his Goulstonian Lectures in 1884 and, while laying more emphasis than Sturge did on peripheral excitation, essentially the same conclusion impressed itself on me before I was aware of his valuable paper on the subject.

It is considered by some physiologists that tactile and muscle sense sensations travel up the cord to the brain by way of the vesicular column and the gracile and cuneate nuclei, while sensations of heat and cold pass up through the grey matter to the optic thalamus. If this be so it may explain the alterations in the temperature sense in lesions of the cord involving the grey matter such as syringomyelia, but the degree to which such lesions influence the temperature sense in the viscera is for many reasons difficult to determine. It is difficult, indeed, to test the temperature sense in syringomyelia even of the stomach much beyond its cardiac end and even here we have the complicating condition of nerve-supply from another source above the seat of lesion. The temperature of hot and cold drinks may be appreciated in the stomach, but beyond it the warmth of the body in the case of cold drinks, natural loss of temperature in the case of hot drinks, and the comparative and normal insensibility of viscera generally soon seem to render the temperature indifferent and its perception impossible. It may be shown, however, in syringomyelia that while the surface exhibits abnormalities and loss of temperature sensation the temperature of imbibed material is still felt by the stomach and this retention of sensibility is probably due in some cases to the pneumogastric innervation of the viscera.

The association of cephalic parræsthesia with visceral disorders is a subject of interest. The situation and characters of such sensitiveness have been carefully studied by Dr. Head,[9] who has been the most recent observer to point out the situation of hyperæsthesia in the surface of the head in connexion with visceral disorder and has given anatomical reasons for the concurrent implication of the sensory nerves of the scalp. Such sensory points in connexion with visceral disorder undoubtedly occur as also do hyperæsthetic points on the thorax and trunk in connexion with cardiac and other visceral disease and disorder, but in a large proportion of headaches, chestaches, and trunkaches pain with little or no tactile hyperæsthesia or hyperæsthesia difficult to detect and delimit is, so far as my experience goes, the rule. This association of visceral disorder with cephalic pain has long been known and some forms of it have been carefully described. Pain in a certain proportion of these cases is probably meningeal, not cutaneous, and from its intracranial situation not accessible to tactile investigation and therefore not objectively hyperæsthetic. While searching for the innervation of the pial vessels I likewise investigated the innervation of the pia mater and found that the nerves which have long been known to course through it end in it by plexus, as I have stated in the *Edinburgh Medical Journal* for November, 1898. Some headaches, therefore, and the pain of meningitis are explicable by the copious innervation of the membranes of the brain and the neural pathology of the investment of that organ is thus brought into line with painful affections of the pleura and peritoneum. The severe headache of tertiary specific disease may in some cases be meningeal, but as the brain differs from other organs in being the seat of perception and the focus

for the sensory channels of the body it is probable that in the case of this viscus disease implicating the structure of its centres and nerves may cause pain in a manner in which a similar lesion would not do in the case of other viscera. The determining factor for local pain in the latter I have argued is a simultaneous tension which increases the force or degree of impression, and in the case of visceral muscle a reflex cramp which squeezes nervous end-organs.

In speaking of the general trophic influence of disease of the central nervous system it was pointed out that pain and mental anxiety were the chief determining factors under these circumstances and that mental anxiety might be regarded as having the same relation to the intellectorium that pain had to the sensorium; that they were in short both painful emotions. Laycock, indeed, called mental anxiety *phrenalgia*, and considered depression of spirits and hypochondriasis varieties of that species of pain.[10] As the brain, moreover, is compact of many organs or, as I shall term them later, organules which concur to produce that multi-unity, the mind, which can distinguish the effects of the exercise or want of exercise of one organ or centre from those of another such as the different effect of the various special sense centres, so it is probable that the direct effect of the disorder of one viscus may impress the mind differently from the disorder of another, the harmonious and painless operation of all being necessary for that unconsciousness of the existence of a particular viscus which is characteristic of vigour and health. Some organs, moreover, like the liver and kidney, the functional activity of which influences the character of the nutrient fluid for the whole body, have when diseased a more depressant general influence than disorders or diseases in those organs which are chiefly mechanical or more specialised in function and effect. The attitude of the patient to disease is also no doubt modified in a measure by the condition of the mental organ itself. The naturally blunt and stupid who fail to appreciate the general gravity of their situation have also probably a minor power for the appreciation of discomfort and may exhibit a callousness in physical distress only attained in the more sensitive and gifted after a philosophic estimate of their general relation to things and time. But putting aside stupidity and philosophy the hope to live or desire to die as influenced by disease or disorder of particular organs is largely dependent upon the circumstances whether such disease or disorder saps energy or produces pain beyond a certain point which is open to individual variation. A pronounced and protracted sense of feebleness is little, if at all, more endurable than actual pain, and disease which engenders such induces a mental depression and despair of vigorous life more certainly than many more serious diseases which have not that specific effect. The suicide of the so-called convalescent from influenza—not an uncommon event—is an instance of this, and prolonged enfeeblement in general from any cause, with its concomitant discomforts and disillusionments, is productive of a misery which the serious disorder of a particular organ which does not rapidly and profoundly enfeeble or cause pain to a certain degree does not induce. Thus the cardiac sufferer whose natural vigour is good and whose diseased heart is well developed and has at times been well compensated, may evince much less and experience less distress than the patient who has experienced angina vera for the first time. Nothing has struck me as being more pathognomonic than the expression and general attitude of some patients on their first experiencing that form of cardiac anguish. It is like a "bolt from the blue" in their lives; they have never experienced anything similar before; the cloud-curtains of the unknown seem suddenly about to be raised and it fills them with an anxious astonishment which frequently on a repetition of the phenomenon plunges them into an acute despair, until the innate bravery of man at his best enables them to face that as any other contingency with indifference and with such aid as it is the privilege of the physician to be able to render. Chronic dyspeptics, again, with their minor but constant dysæsthesiæ with periodical exacerbations and imperfect hæmopoiesis, frequently develop a mental habit which renders them, like one of the most distinguished of them to whom we can forgive much, "gey ill to live wi'."

On the other hand, chronic disease which attacks youth is not associated with much pain and only deteriorates vigour in such a manner that the perceptive power of the individual does not appreciate great differences in this respect, may be coupled with all the sanguineness and natural expectation of life and usefulness which is proper to that period. The expectation of recovery of the phthisical, even in the last stages of the disease, is so well-known and common a phenomenon as to have become stereotyped in clinical language. There is no doubt under all these circumstances, except in the case of the stupid, a so-called metaphysical element in the manner in which the mind is affected by organic disease, but it may I think be regarded as based upon clinical facts that the mind appreciates the necessity for the exercise of philosophy least readily, as is most reasonable, when visceral pain and rapid enfeeblement are not dominant characteristics of the type of disease from which a given patient is suffering.

ABSTRACT OF AN

Address

ON

THE WORK OF THE GENERAL MEDICAL COUNCIL.

Delivered before the Manchester Medico-Ethical Association at the Memorial Hall, Manchester, on Dec. 16th, 1898,

BY VICTOR HORSLEY, F.R.S.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—I had the greatest pleasure in accepting the invitation of this association remembering as I did the numerous pleasant occasions on which I have visited Manchester, especially in relation to the question of medical politics. To begin with I will just sketch out to you the lines on which I propose to occupy some of your time this afternoon. In the first place I wish to draw your attention to numerous defects in the procedure of the General Medical Council in the hope that by the publication of a few of these we may secure further reform. Then I wish to proceed from that to dwell on the way in which this publicity of these defects may be secured, and then to pass on from that to discuss some of the criticisms of my views on the General Medical Council and its work and, lastly, to pass to the large question of the amendment of the Medical Acts. I find that that would practically fill up the time that I can justifiably occupy. I know there are other matters of vital interest, but it seemed to me that if you would raise them by asking me questions we might expedite business.

The General Medical Council is an extremely curious body; it is unlike any other public body of men collected for public business I have ever come into contact with. Its duties, according to some persons, are those of superintending the education of medical men and registering them when educated, and for a long time these were regarded as the only objects of the General Medical Council. I think the members of the General Medical Council when they sit in the Council chamber collectively forgot their duty towards their neighbour; they forgot that by having entrusted to them the control of the Register that duty carried with it the necessity of observing the difficulties and dangers which affect the medical profession as a whole. For a long time they took no notice of these difficulties and did not seek to ameliorate the condition of the medical profession. For the last four years a change has occurred. There is a growing feeling, which is stronger at each session, that the responsibilities of the Council towards the profession are very real and require a larger proportion of the Council's time and attention. As regards, however, the procedure of the Council in its work it is unlike that of any other public body. It would astonish you to hear, for instance, that there is no record kept of the statements made in the Council chamber; there is no shorthand note of public meetings or private meetings; the only record that exists is what is published in the medical journals. In regard to the delicate work of the Council—namely, the penal matters—there are some standing orders in regard to these cases, but apart from these there are no regulations and the action of the Penal Cases Committee is uncontrolled. It used to be declared by

Digitized by Google

some members of the Council that the Penal Cases Committee was a kind of grand jury and every member of the profession consequently felt that if there was a grievance lodged against him it went before such a grand jury of his compeers for consideration. As a matter of fact it is authorised to act in this way, but the conduct of its business is wholly without rules. I succeeded last session in carrying a resolution whereby the Penal Cases Committee should report at the next session of the Council as to what procedure they do adopt. Upon that report I intend to bring forward such reforms as have occurred to me and which I know are occurring to other members of the Council in regard to this serious division of our work. There is another matter of congratulation in relation to penal cases procedure which I may refer to. Hitherto for some unexplained reason the Penal Cases Committee has not been elected annually and therefore has never been practically altered since it was constituted except by the death of one President and the election of the present President. I proposed at the last session that this should no longer be the case and that the committee should be renewed annually, and no one advanced any sound reason why this should not be done. It is hardly necessary to say, however, that when I first put forward this resolution it was temporarily shelved for six months and that the Executive Committee to whom it was referred did not think it advisable to make any alteration in the mode of election, but despite opposition I am glad to say that my proposal which was adopted by Sir Richard Thorne and moved by him as an amendment was carried by a large majority. Now the Council will have the opportunity of electing the members of the Penal Cases Committee every year or of not electing them as may be thought fit. This is a distinct step forward. Now to return to the question of characteristics of the procedure of the Council, I must of course allude to a prominent and disagreeable feature—namely, secrecy. You will have seen from the reports of the last session that very definite steps are being taken by certain members of the Council to introduce more and more difficulty in the way of anyone getting to know what is going on in the Council or of anyone (who has a right to know, such as registered practitioners) knowing what is about to go on which is of importance, because if a man has an interest in any matter before the Council he may naturally wish to go to the Council chamber to hear it discussed. This applies to us specially as registered practitioners, but it applies also to the public, and it is commonly forgotten by many members of the Council that they are a statutory body commissioned by Parliament to deal with *public* moneys, which moneys are not primarily the moneys of the Council; they are national funds, subscribed by members of the profession and paid by them as earnest-money when they register their names; therefore any discussion with a prospective or current concern in the spending of these moneys should be open to the general public, and the general public for the same reason have a right to know when a financial question is to be discussed. What was the arrangement in this particular up to the last session? Up to this session anybody who went to the public gallery of that Council and wishing to know what was going on asked in a courteous way in the office for a programme of the public business was handed a programme of the business. I am sorry to say that at this session under the recently established *régime* we discovered on the second day that members of the profession who came to the public gallery were refused programmes by the officials. I brought the matter up and I was informed by the President that programmes were never given away at all and that they had never been given away. I promptly refuted the denial, but in spite of what I said the statement was reiterated by the Registrar, chiefly in consequence of whose inaccuracy I lost my motion, though the President stated as an argument against me that the programme was a confidential document because the word "confidential" was written across it. I therefore there and then asked the legal assessor of the Council whether the printing of the word "confidential" across it made it confidential and he said of course it did not, though he conveyed the idea put forward by the official party that it would be just as well perhaps if the people in the gallery did not have the document. But the fact remains that public moneys are expended and public business is transacted and yet not only the public but registered practitioners are not permitted to see the programmes which are no more confidential than an ordinary newspaper. I dare say in a year or two we shall have this put right, but it is one of the attempts to conceal the Council's actions which is temporarily successful. The actual conduct of some of the proceedings *in camerâ* is of course obligatory in regard to penal cases, but there are many subjects discussed *in camerâ* which are on the borderland and ought not to be discussed *in camerâ*, but such is the alarm of certain members of publicity that they move the Council to go into camera, and the majority of the Council are so easily terrified by questions of law which are common knowledge to most people that they support the motion and the matter is smothered for a time. There are many signs which indicate that there is a strong wish to introduce what may be called Dreyfusian tactical proceedings into the Council. The President asked this session that he should be given more discretionary powers and he ruled out of order a resolution of mine which being perfectly in order will require discussion next session. The Executive Committee which was originally appointed to shorten the Council's work now by the nature of its reports lengthens the work. I moved last session sundry reforming resolutions which the Executive Committee reported upon in an obstructive and destructive sense which only caused a discussion of some hours with the result that we gained about 70 per cent. of the points and in the teeth of the Executive Committee's hostile recommendations. Among these, for instance, I proposed that the members of any committee should have an opportunity of calling their committee together if several of them thought fit. Whereupon the Executive Committee sought to again centralise the power to the chairman by proposing that he alone should have authority to convene a meeting. This somewhat comic act of obstruction was defeated as it deserved.

Another curiosity with regard to the procedure of the Council is the document question, but I am not going to weary you with all the details, for I have reported how the present state of affairs stands in my Report to the Registered Practitioners, but will pass to the question of delay of business in the procedure of the Council which is very serious. It is due to several factors. In the first place the members of the Council are not informed between the sessions of what is going on—they come to each session as it were like boys coming to school for the first time, excepting of course those members of any special committee to whom some small piece of business happens to have been referred. The papers are in the hands of the Registrar, who is a paid servant of the Council, and he enjoys the privilege of studying the papers which privilege by the action of the Standing Order of last session is refused to the members of the Council. That is the condition of affairs. On this latter point I was much amused to note the wording of the resolution which was carried by Sir Richard Thorne—namely, that the working of the Standing Order inhibiting and obstructing the inspection of documents was not *altogether satisfactory* and that it was desirable to facilitate the inspection. That is now to be done by a report of the Executive Committee next session. The reports will probably result, as before they have resulted, in putting the brake on, but at any rate we must be thankful for small mercies. This is the first official step down from the unwarrantable position assumed by the President last session.

[Here Mr. Horsley criticised the reports of the meetings of the General Medical Council which appeared in the *British Medical Journal*, finding them "very meagre" but adding that "not a word can be said against the accuracy."]

That brings me to the all-important question—namely, the question of the amendment of the Medical Acts—because I was agreeably surprised and pleased to think that I could detect in the Council at the last session a distinct glimmering of light on this subject. Of course, you have no time to read the minutes of the Council, but if you had you would have found that the legal assessor stated three years ago that in his opinion there was no necessity to amend the Medical Act. This statement was made in answer to a document from the Medical Defence Union pointing out a failure in the prosecution of an American quack and of a person struck off the Register for practising under a foreign degree who was not registered and that the Act had been seriously injured by the remarkable finding of the stipendiary magistrate of Cardiff. Three years ago the Council did not care anything at all about the matter and the legal assessor gave the opinion I have referred to. I am very glad to say, however, that in the last session I succeeded in getting him to withdraw from that absolute position. It was another instance

Digitized by Google

of giving way to stress of political weather. The Council had had laid before them the important case of the prosecution of an unqualified man at Norwich who was successfully prosecuted under the Apothecaries' Act and fined the full penalty, but as regards the Medical Act though he called himself both "doctor" and "surgeon" the magistrates held for some unexplained reason that he had no right to call himself a "surgeon" but that he had a perfect right to call himself a "doctor." I will say at once that this case brought home to the Council the point which has been the point of battledore and shuttlecock judgment in the courts for years—namely, the act of a person being "wilful and false" and the difficulties which are caused by the absolute decisions of magistrates deciding in cases. If a magistrate decides on a question of fact then there is no more to be said; if you appeal to the High Court all that is said is that the magistrate decided on fact and there is no help or hope for anyone and that is what happened in this case. The magistrates apparently were extremely friendly towards the defendant and they refused to state a case in the form I have told you. Such decisions are nothing less than driving a coach and horses through the Act of Parliament. This case unquestionably impressed the Council and especially because it was pre-eminently a matter of "title" and I think that the first step we must take if we want to obtain an amendment of the Medical Act is to first convert the General Medical Council to the necessity of the case and with this glimmering of light that I have mentioned we may see our way to advance a little further. There is another reason for first converting the Council. The Council is continually brought into communication with the Privy Council and under these circumstances the Privy Council naturally refers to the General Medical Council when it wants to know anything concerning medical legislation. It is obvious, therefore, that if the British Medical Association brings out an Amendment Bill, as I hope it shortly will, and sends it to the Privy Council it would be referred by that body to the General Medical Council. Moreover, to obtain our object we must bring influence to bear on the Government and the Council certainly has some influence with the Government; unless therefore we persuade the Council first we have little chance of the Government taking the Bill up as a Government measure and without that there is hardly any other way to pass a Bill. Therefore we must work to convert the Council to accepting the view of an Amendment Bill. I have already told you how the Council was in years gone by hostile to interfering with the Act at all, but that was chiefly because in those years the General Medical Council objected to safeguarding the rights and privileges of the practitioner. Now there is a change and I should say probably the large majority of the Council are sincerely anxious to protect the privileges of the practitioner. Now what ought an Amendment Bill to contain? Years ago among the various Bills that were proposed in the British Medical Association and out of it there were three points always prominent which points also appeared in the addresses of candidates for the direct representation of the Council and were as follows: the first was the question of representation in the Council, the second was the one-portal system, and the third was the safeguarding of registration.

As regards the representative or rather non-representative character of the Council Mr. Brown has put forward at different sessions of the Council a resolution that the Council should act under the powers under the Act of 1886 and appoint three more representatives, but that motion has never yet received a hearing; it has always been shelved. Towards the end of the session the President has usually made pathetic appeals to Mr. Brown to withdraw the notice on the ground that the time is too short. Though Mr. Brown, I believe, now quite intends to press the matter at the next session I am afraid it will be defeated so that we cannot reasonably look for help in that direction. But a new Bill might abolish all the representatives of the corporations and make the whole body of the Council truly elective and thus we should have representation in the highest degree. A second way would be that Section 4 of the Medical Act, 1858, which affects the constitution of the Council in regard to the representatives of the different bodies, should be amended so as to carry out its original intention. That Section states that a representative shall be chosen by each of the following bodies and that word "bodies" most of us hold to mean the whole body politic of each corporation. However, as you know well, the central councils of these corporations have, so to speak, grabbed the position and have refused in any way to consult the members of their corporations in the election of their representative. There is of course the remedy of going to the High Court, but that, I think, would be simply throwing away good money. It would be necessary therefore that an Amendment Bill should contain such wording as would make Section 4 of the Act of 1858 clear beyond dispute and that the election should be placed in the hands of all members of such bodies. This matter of representation rather hangs with the next question—namely, the one-portal system—because if the one-portal system were carried the Government would doubtless see that there was no reason for the representatives of the corporations being directly elected at all. I am bound to remind you that these gentlemen have constantly denied that they are representatives of such and such a corporation ever since Sir Dominic Corrigan once said that their discussions were nothing but battles of the shops. Nevertheless, we have occasionally at each session this shoppy character coming up. Last May session we had a strenuous dispute between the College of Surgeons of Edinburgh and that of England and at this last session also we saw the Crown representative of Scotland who spoke in the name of the Scotch schools as though the Scotch schools had been unfairly treated in relation to the examination for entrance into the services. These were instances of this shop feeling and so long as any representatives are elected by a small body such as councils of these corporations are they must inevitably have a relatively narrow view of things tinged by the colour with which their college happens to paint them.

In regard to the one-portal system for many reasons we must have an equalisation of the qualifying examination. The present system is wholly unjust and the practical question is what attitude does the Council bear towards it? I think the attitude at the present moment is rather favourable, though there is no doubt that the present Council will have nothing to do directly with any preliminary examinations, but though they dismissed a motion by Sir Christopher Nixon and myself a few sessions ago dealing with that point they rejected it in such a way as to show that the feeling existed that perhaps the one-portal system might be tried with advantage in the final or qualifying examination. If we pursue that line perhaps we shall find that the Council may be converted to a one-portal system. The President some years ago said to me at Liverpool that he would shed his last drop of blood against the proposal—and that is doubtless the feeling of the Scotch schools—but the equalisation of the character of the qualifying examination is so desirable a thing that the unreasoning opposition of any school need not be feared.

Next, as to the protection of our hard-earned privileges I must say that even now it seems to be thought by some leaders of the profession that there is something degrading in endeavouring to protect our privileges. If we have privileges we ought to protect them, is the view I take up, and I certainly object to a medical man being considered to be fairer game for exploitation than any other professional man. Still, it is the fact that there are leaders of the profession who hold the pessimistic view, and I mention the existence of this idea because I think it is our duty to endeavour to remove that idea wherever it exists, and here I think private influence on the part of the profession can do a great deal. The men we wish to influence come into contact with the people connected with the Government offices and they can exert a notable personal influence in some cases. This is a factor that is not to be disregarded from a political point of view, if we are to push forward the attainment of the amendment of the Medical Act, and undoubtedly this plan of privately influencing the leaders of our own profession would have much success and should be actively pursued. The chief privilege that has to be protected is of course practice and our first thought should be how that is to be safeguarded. Evidently in view of the conduct of the magistrates I have quoted above we must secure a re-drafting of Section 40, for if it be possible for a magistrate to state as a judgment that which is patently absurd, then it is clear that the Act on which he bases that judgment is capable of misinterpretation, and if so it must be corrected. I do not admit, and I never shall admit, that the reading of Section 40 could lead to misinterpretation by any ordinary person who reads it carefully. However, we have to take things as we find them, and as the Norwich case is the second occasion on which a magistrate has misinterpreted it it is clear that it

Digitized by Google

must be amended so as to make it clear to the magisterial mind. How we are to get forward and how we are to convert the Council is another matter. I think the Council should be approached in this sort of way. The branches of the British Medical Association ought to hold medico-political meetings as well as scientific meetings and at these medico-political meetings they ought to pass resolutions and not merely send them to the council of the association, but also send them to the members of the General Medical Council. Undoubtedly such communications gradually make some impression and turn the attention of the minds of the Council to the fact that the profession is feeling keenly on the matter. The worst argument that we have to deal with is that the profession does not care, and this statement is a peculiarly difficult one to put aside in a public debate unless we have distinct resolutions before us which have been framed at meetings and sent to the Council. I have already alluded to private influence brought to bear on the members of the profession who are not members of the Council—I should like to apply exactly the same line of argument towards those members of the Council with whom professional men are personally acquainted. Lastly, much good can be done by the members of any given corporation meeting together and passing resolutions to be sent to the council of their corporation to be sent on to the General Medical Council. Many of these representatives of the corporations in the General Medical Council say they never hear anything from the members of their corporations and therefore they can only assume that the members of the corporations are perfectly satisfied with what the Council does. I have repeatedly had this said to me at the Council and of course it cannot be completely answered except by the votes of the members of such corporations. My last word I have to say this afternoon is that if such meetings and such resolutions are passed relative to any given matter as I hope will be done in the Hunter case when the full facts are laid before the profession and if these resolutions are published in the papers, that will influence the Council and by such means you will support your direct representatives in the Council. They are in a minority and they feel in the minority occasionally, but they do not regard it as a hopeless minority if they have the support of their constituents.

INTERSTITIAL HERNIÆ AND THEIR TREATMENT.[1]

BY W. McADAM ECCLES, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL AND TO THE CITY OF LONDON TRUSS SOCIETY AND DEMONSTRATOR OF OPERATIVE SURGERY AT ST. BARTHOLOMEW'S HOSPITAL, ETC.

I HAVE to thank you for the honour you have done me in allowing me to read a paper before this ancient medical society, one of the oldest in the kingdom, founded as it was in the year 1794. The subject which I have chosen is one that I hope will prove of interest, for so far as I know it is not often dealt with and yet it is of considerable importance. Herniæ are sadly too common, inguinal herniæ form a large proportion of these protrusions, and inguinal herniæ assume an immense number of variations. It is to one class of these that I would direct attention in this paper—interstitial inguinal herniæ.

By the term "interstitial" is meant an inguinal hernia, a part or the whole of the sac of which lies in the planes of the abdominal wall. Normally—if one may use such an expression for a lesion—the parietal peritoneum which in an inguinal hernia is stretched and displaced until it traverses the inguinal canal remains either confined to that passage or transgressing the outlet, the superficial ring, reaches the scrotum or labium. Here is the well-known complete inguinal hernia. But suppose that for some reason—and what these reasons are will be observed later—this peritoneal pouch instead of making its exit from the canal dissects up one or other of the planes of the anterior abdominal wall; it is then justly spoken of as an interstitial sac. Such an abnormal position of the sac of an inguinal hernia is not so very rare and it is because its presence may lead to very grave consequences that I venture to bring forward the subject. Interstitial herniæ are usually classified under three varieties: (1) where the adventitious sac lies in the plane between the internal and the external oblique muscles of the abdominal wall; (2) where the sac is placed between the external oblique muscle and the superficial fascia and skin; and (3) where the peritoneum forms a pouch in the extra-peritoneal tissue and therefore between the peritoneum and the fascia transversalis. Of these three forms the first is undoubtedly the most frequent and the last that which is the least often recognised.

CAUSATION.

As to the causation of interstitial herniæ much speculation still exists. Congenital inguinal herniæ occur in large numbers and in the male infant they are generally associated with some want of proper development. This defect not infrequently shows itself in the arrest of a testis, sometimes in the inguinal canal, sometimes just external to the superficial ring, and occasionally within the abdomen. Now interstitial herniæ in the male sex are so commonly accompanied by an abnormal position of the testis that it would seem that there is a causal relationship between the two conditions. But interstitial herniæ occur also in women and, comparatively speaking, more frequently in this sex than in the opposite one. If 1000 cases of inguinal herniæ in females be taken—and perhaps I may remark here in passing that inguinal herniæ in the female subject are more frequent, if all ages be taken into account, than are femoral herniæ,—if 1000 cases therefore are examined in the female it will be found that about 6 are of the interstitial variety. But if a similar number of inguinal herniæ in the male sex be observed it will be only one that is of the interstitial form. The occurrence of interstitial herniæ in the female sex obviously disposes of the fact that partial or complete rentention of the testis is the sole cause of an interstitial hernia being formed. But the question that will at once present itself is, Are these cases of interstitial herniæ in women associated with a congenital herniation of the ovary? As far as I know this has not been demonstrated to be the case.

What, then, is a common factor which can be found in both sexes and one which may be taken as a cause? It will, I think, be found in the circumstance that in almost every instance of interstitial hernia, at any rate of the first or second varieties, there is a patent processus vaginalis or canal of Nuck. The case may therefore be stated thus: given a male infant who has a fully descended and properly developed testis, even if he has a processus vaginalis, yet he is very unlikely to be the subject of an interstitial hernia, though he is likely enough to acquire an ordinary variety of such a protrusion. On the other hand, take a male child, particularly of a few years of age, who has still an open process and an only partially descended testis, then will be present just the conditions which tend towards the formation of an interstitial hernia. The unclosed process of peritoneum allows the descent of viscera, the abnormally situated testis prevents the passage of the same into the scrotum. As an instance of this I may allude to the case of a young man, aged twenty-six years, whom I recently saw with an interstitial hernia of the first variety. As long as he could remember he had had a swelling in the right groin and at the age of ten years he commenced to wear a truss for the same. He was also confident that up to the age of sixteen years he had never been able to feel the right testis in the scrotum, not even at its upper part. When I saw him at the age of twenty-six years he had a well-marked interstitial hernia and the right testis, although smaller than the left, was well into the scrotum, at a position where the patient averred that he had only been able to feel it since he came of age. In this case probably the sequence of events was as follows. He was born with his right testis just within the superficial ring, together with a patent processus vaginalis reaching to the end of the canal. Into this there protruded at an early age some of the viscera of the abdomen. Then seeing that the testis blocked the way at the exit of the canal and that the intra-abdominal pressure was ever at work above the peritoneum was gradually stretched in the line of least resistance—namely, into the plane of the abdominal wall between the internal and the external oblique muscles. Still later the force of the protruding contents of the sac led to the testis, although tethered by its cord, being forced through the ring into the upper part

[1] A paper read before the Plymouth Medical Society on Nov. 9th, 1898.

Digitized by Google

of the scrotum, with the formation of a short scrotal portion of sac.

But I have now to consider what is the second cause at work in the female sex in the production of an interstitial hernia. It has already been seen that in this sex, as in the male, there is usually present a patent process of peritoneum, but there is no herniated ovary to take the place of the partially descended testis. In the female, and especially in the female infant, the superficial ring is less of a real opening than it is in the male. In this fact, then, probably lies the cause that we are in search of, for as in the male the testis blocks the way, so in the female the narrow aperture bars the exit of the hernia and the peritoneal pouch is forced again in the line of the least resistance. In females interstitial herniæ rarely assume any large proportions till adult life has been reached.

There are two other possible causes of interstitial herniæ and these may both of them act in either sex, but perhaps only in adult age. The first of these is the action of an ill-fitting or improperly adjusted inguinal truss. If, as is so frequently the case, it happens that a measure is taken for the truss which is of too great a length it will necessarily follow that the pad of the instrument will come to lie over the superficial ring. The effect of this in an oblique inguinal hernia may be to effectually prevent the descent of the viscera through the exit of the canal, but to offer no protection against their prolapse into the canal itself through the deep ring. Thus the intra-abdominal pressure may gradually provoke the formation of a secondary pouch from that part which lies in the canal. Again, supposing that a truss, properly formed and accurately measured for, is adjusted too low down so as to lie once more over the superficial ring, and not over the deep ring and the canal, exactly the same circumstances may occur. The second cause that should be mentioned is *réduction en masse*. If this is produced by forcible taxis, so that the original sac is dislocated from below into the tissues constituting the abdominal wall, doubtless a rare form of this not frequent accident, it will follow that in reality an interstitial hernia is formed and one which may be termed a traumatic interstitial hernia. Interstitial herniæ are more common on the right side of the body than on the left, probably for the reason that the right testis is more frequently arrested than the left.

SIGNS, SYMPTOMS, AND DIAGNOSIS OF INTERSTITIAL HERNIÆ.

1. The first variety of this form of inguinal hernia has a ventral swelling, but one that is not so apparent as that which occurs in the second form. The swelling that is so distinct in the adult will in the infant be but slight and it is this fact that leads to this class of hernia being overlooked in its early stages. But if the conditions which are favourable to its production are present it may be surmised that it is probable that the hernia may be developing. The projection in its more advanced stage presents itself as a flattened oval tumour, which lies above and parallel to Poupart's ligament and extends upwards and outwards towards the anterior superior spine of the ilium. Occasionally the direction is towards the umbilicus or nearly vertically upwards. The reason of the passage of the sac outwards is probably that it is the line of least resistance, since the muscles are less closely applied to one another in that region than towards the linea semilunaris. If a patient who is the subject of this form of hernia be requested to assume the horizontal posture most if not all of the swelling will disappear, but if then he be asked to cough a characteristic sign will present itself. As the expulsive efforts are made the viscera descend and then gradually, as it were, dissect up the plane of the abdominal wall towards the anterior superior spine. I have seen one instance where this dissection was very slow, but in the end reached almost to the level of the umbilicus. Sometimes in addition to the portion of the sac that is seen on the abdominal wall there is a part that reaches into the scrotum or labium. If such is present often a very distinct groove marks the limit between the two. The muscles which lie in front and behind the sac in the ventral region are not infrequently much atrophied, so that when they are put into action no very great amount of hardening is felt over the swelling. This first variety of interstitial hernia is usually completely reducible, for the mouth of the sac is generally of some considerable size. Strangulation, however, does occur and when present it may be very severe. There are but few conditions which are likely to be mistaken for this form of inguinal hernia. Indeed, the characteristic shape of the tumour, its evident connexion with the abdominal cavity, and the way in which it appears when the patient coughs, all go to make its recognition a matter of ease. An abscess of the abdominal wall, a collection of pus which has had its origin within the abdomen, a large hydrocele of a patent processus vaginalis of a partially descended testis and a hæmatoma are all swellings which may occur in the same region, and although it is unlikely that any one of them should be taken for the hernia yet it is not so uncommon for the hernia to be thought to be one of them. Obviously an error in diagnosis of this kind might lead to very serious consequences.

2. The second variety of interstitial hernia has also an external swelling and one that is usually, at any rate in its later stages, very well marked. The projection has, moreover, the appearance of being more superficial and can be traced to the superficial ring, which is often of considerable size. Like that of the first form it has a tendency to progress towards the anterior superior spine of the ilium, but the reason why it should take this course is not so clear as in the former case. It may be that the superficial fascia is less firmly fixed to the aponeurosis of the external oblique than elsewhere. The swelling is not so flattened and there is no hardening of muscle over it as in the first form. There is much more usually a part of the sac in the scrotum in the second variety. It is probable, because adhesions have formed at the upper portion of the scrotum or labium, that the secondary sac has been added to the original one. Occasionally the swelling may be so large and pendulous as to hang over, that is in front of, Poupart's ligament and thus to simulate a femoral hernia. This peculiarity may lead to a vertical incision being made for the relief of strangulation, especially in the case of women. The second variety of interstitial hernia is rather more liable to strangulation than is that which has been above described, but the contents of the adventitious portion of the sac are usually reducible. The differential diagnosis of this form of inguinal hernia is analogous to that of the preceding save for the fact that it may have to be distinguished from a femoral hernia. This may be readily done by observing that the bulk of the swelling has its site well above Poupart's ligament and that the base of the tumour is in the same region. In the male subject it is generally easy to slip the forefinger into the inguinal canal and thus prove that it is empty and that a femoral hernia exists, but in the female this is not so readily accomplished.

3. The third variety of interstitial hernia, in which the additional sac lies in the extra-peritoneal tissue, has no external or ventral swelling, and, as has been indicated, it is rare for this to be recognised except as the result of operation or after death. The secondary pouch in these cases is most usually found in the loose tissue of the iliac fossa, but sometimes it passes between the bladder and the body of the os pubis. In most of these instances of pro-peritoneal herniæ, as they have been termed, there is a sac in the scrotum or the labium. It is difficult to decide in many cases which is in reality the first part of the bilocular sac to be formed. There is the original process of peritoneum in the inguinal canal and probably in most instances this is prolonged into the scrotum or labium, and then possibly as the outcome of adhesions and irreducible contents the secondary sac is gradually formed in the lax tissue of the sub-serous layer of the abdominal wall. One of the chief interests of this third form of interstitial hernia is the fact that this hidden portion of the sac may give rise to the production of one of the varieties of *réduction en masse*. If a scrotal hernia is not reducible spontaneously and taxis is applied the contents of the lowest part of the sac may be reduced, not into the abdominal cavity, but into that part of the sac which lies above in the iliac fossa. Naturally in the case of a strangulated hernia this result is of very grave import, for the surgeon may conclude that satisfactory reduction has been accomplished, whereas what has really occurred is that the contents have indeed changed their location, but they are still strangulated at the neck of the sac. This circumstance which may arise in almost any case of complete inguinal hernia, though undoubtedly it is infrequent, is one of the arguments for the performance of herniotomy in all cases of strangulation in preference to taxis if not otherwise contra-indicated. In a few rare instances a secondary pouch from a femoral hernia has been found lying in the subperitoneal tissue between the os pubis and the bladder. In the matter

Digitized by Google

of diagnosis of the third form of interstitial hernia, seeing that the secondary sac is hidden and unknown, there cannot be any condition from which to distinguish it, unless strangulation is in evidence. Then the case becomes one of intestinal obstruction associated with a hernia which itself may not show many, if any, of the signs of strangulation. I shall allude to this again.

THE TREATMENT OF INTERSTITIAL HERNIÆ.

The treatment of interstitial herniæ may conveniently be divided into two sections: (1) one where the contents of the hernial sac are reducible; and (2) the other where they are strangulated and therefore irreducible.

1. *The treatment of reducible interstitial inguinal herniæ.*—As in the case of any reducible hernia its treatment may be either mechanical or operative. An interstitial hernia is not by any means an easy one to control thoroughly by a truss, particularly if from neglect or otherwise it has assumed somewhat large proportions. There is a tendency for the viscera to "ooze" as it were down into the sac in spite of the pressure of the instrument. In an adult where from any cause an operation is not expedient an interstitial hernia of the first or second variety will have to be treated by the application of a suitable truss. If the ventral swelling is but slight it may be that an ordinary inguinal truss with the usual-sized pad will be sufficient to retain the viscera within the abdominal cavity. As, however, in adults the sac has reached such dimensions that this form of truss is not very efficient it is generally necessary to employ a variety of instrument fashioned after the model of the inguinal pattern with the pad in the form of an interstitial plate. This extends upwards and outwards from the limits of an ordinary inguinal pad. When such a truss is adjusted to the body the plate will lie over the inguinal canal and cover in addition the area which lies directly above and external to it. A like pattern of truss is often a useful one in those cases of traumatic ventral herniæ after some operations for suppurative appendicitis. It may also if made in vulcanite be employed with great advantage after inguinal colotomy. In some instances of the second variety of the interstitial form of hernia a rat-tail truss may be of very good service, especially where there is some considerable scrotal or labial protrusion. The slightly modified shape of the rat-tail, known as the forked-tongue truss, is more satisfactory in other cases. Passing to the operative treatment of these herniæ, it must be said that they are some of those in which operation is not only justifiable but strongly to be recommended, provided that there are no contra-indications. In young male children the subjects of commencing interstitial herniæ, particularly if they have an arrested testis, have a lesion which can be most satisfactorily treated by operation. In dealing with these there are two important points to be discussed. The first is, what should be done with the secondary sac?, and the second, in a male subject what is the line to be adopted with regard to the arrested testis? When a radical operation is performed for an ordinary scrotal hernia it is not usual at the present day to disturb the portion of the sac which lies outside the superficial ring but to make the incision at once over the line of the canal and then to cut off the sac right up at the deep ring. The same principle may be followed in the case of the interstitial hernia. A free incision exposes the ventral portion of the sac but only that part of it which occupies the place where the inguinal canal should be. The region of the deep ring is then laid bare, the peritoneal pouch at its narrow part is removed flush with the anterior parietal peritoneum, but the greater part of the adventitious sac is left *in situ*. There is much less risk in doing thus than in widely dissecting up the planes of the abdominal wall. When the secondary sac lies in front of the external oblique one has to deal with a case which is quite similar to an ordinary oblique inguinal hernia. The neck of the sac is still within the canal and this is freed and cut through, while that portion of the sac which is external is untouched. In the instances of young males it is but seldom necessary to introduce many or even any sutures into the muscles, for when once the stretching force has been removed these structures naturally contract and fall into their proper relations. There has been a congenital opening in the parietal peritoneum; this has been closed and there is no further tendency to the production of an acquired hernia. The second point that ought to be considered is what is the proper line to be taken with regard to the arrested testis. In many cases in children it would be almost impossible to determine accurately whether the testis is normally developed for the period of life. In the adult this is an easier question to answer, but even then it is difficult to say whether a small ill-developed testis may not have the power of secreting spermatozoa. In dealing with cases of arrested testis in radical operations for hernia my usual plan is, if the patient is a child, to always replace the testis in the subserous tissue, while in adults, if the gland is very small, to remove it altogether, provided that the patient consents. By this plan of removal, only of course if the opposite testis is well formed, a very thorough operation on the hernia can be carried out, for the inguinal canal need not in any way be preserved. I do not think that there is much or any benefit, even in infants or young males, to attempt to bring the ill-developed testis down into the scrotum. It is seldom that this can be done perfectly and my own experience is that but little good accrues to the testis which has been so manipulated. Further, I do not think that there is any danger from returning the testis to the extra-peritoneal tissue, where it will lie in comfort and certainly not be more liable to malignant infection than one that is normally placed.

2. *The treatment of strangulated interstitial inguinal hernia.*—Like any other form of hernia, it is when strangulation occurs that the chief danger arises in interstitial herniæ, but there is even greater gravity in the strangulation of these special herniæ than there is in those of the more ordinary varieties of protrusions. Here there are often sacs, part of which may lie hidden and part of which may contain bowel which is nipped while other portions are free from the constricting force. For the two former forms of interstitial hernia the treatment when strangulated differs but little from that which would be followed in the case of an inguinal hernia which presented no peculiarities. Taxis is not to be recommended, I venture to believe, in the majority of strangulated herniæ, but it is particularly to be avoided if possible in these interstitial ones. Operation should be undertaken at the earliest opportunity and an attempt made after relieving the constriction and returning the contents of the sac to radically obliterate its neck. Great care has to be exercised if taxis is employed not to mistake the reduction of the contents of one part of the sac into another portion as complete return of the viscera into the abdomen. Again, the same caution must be taken when operating to be fully satisfied that all secondary parts of the sac have been thoroughly explored so that no imprisoned bowel may remain unobserved. In instances where there is a true pro-peritoneal sac in addition to a scrotal, or labial, one, the condition which occurs when strangulation takes place in the hidden part is a difficult one to diagnose with certainty. Generally speaking there will be all the signs of intestinal obstruction, but without the local ones of strangulation in the visible sac, which, however, may present some signs of inflammation. These cases should always be explored in the inguinal region without delay and if no secondary sac containing intestine is found then the case resolves itself into one of intestinal obstruction, the cause of which must lie within the general abdominal cavity, and an immediate laparotomy is called for. The actual strangulation in the third variety of interstitial hernia is usually at the common neck of the sac, but occasionally it is to be found at the entrance to the secondary hidden sac. In cases where *réduction en masse* has occurred and is evidenced by the continuance of symptoms of strangulation it is necessary to perform an operation and that without any delay. Thus the strangulation of an interstitial hernia is to be regarded with extreme suspicion and the prognosis which is given to be one of a guarded nature.

In conclusion, I hope that even if this paper has in it not much that is new, yet that there may be something of practical interest to each one of us, for we may be any day called upon to treat such a form of protrusion as that known as an interstitial inguinal hernia.

BARRY ACCIDENT HOSPITAL.—At a meeting of the Barry District Council held on Dec. 9th it was decided to send a deputation to the Local Government Board with regard to the erection of a small-pox hospital for the town and also in reference to the proposal that the accident hospital at present maintained by voluntary subscriptions should in future be carried on out of the public rates.

AN INQUIRY INTO THE PRODUCTION OF BLOOD PLASMA—ITS VITAL PROPERTIES AND MODE OF NOURISHING THE TISSUE.[1]

BY THOMAS GLOVER LYON, M.A., M.D. CANTAB.,
PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

IN former days the blood with its humours, fluxions, serosities, and viscosities was regarded as the seat of life, health, and disease. Prince Henry, speaking of his dying father King John, says: "It is too late; the life of all his blood is touch'd corruptible." The discovery of the circulation of the blood added other factors—a pumping apparatus and tubes with the necessary adjustments. It has only lately been proved that the parts in general performing the functions of the body are microscopic elements placed in definite arrangements and held together by connective tissue. This conception of active organs has now so completely seized on the scientific mind that it seems an unwarrantable presumption to claim for a fluid definite vital properties. There is, however, a half-way house in the matter. Red blood corpuscles are recognised as unnucleated vital bodies budded off from nucleated cells, and I hope to show that masses of protoplasma, minute compared with the blood corpuscles, moving freely over one another and thus forming a fluid, may possess vitality and perform vital functions. I shall for the sake of discussion, as far as possible, divide this paper into statements and arguments and for the sake of clearness assume living matter to consist of bioplasm holding in its meshes formed material. It is not intended here to enter into the abstract question of vitality. The word "vital" is used in relation to certain properties of what is called "living matter" which seem not to be possessed by the same matter after a quick change called "death" has occurred.

General statement.—I. Blood plasma consists of minute particles (plasmacules) varying in composition within very small limits which consist of bioplasm in vital relation with formed material, water, and salt. These plasmacules glide freely over one another forming a fluid. II. They possess definite vital properties—viz., vital molecular inertia, vital contact-attraction, and the power of zoosmosis. III. They are formed by a budding off from or liquefaction of the outer part of the cells of the retiform tissue of the intestines which have assimilated a part of the digested food-stuffs. IV. They are renewed by the cells of the lymphatic glands and the white corpuscles. V. The formed material is passed from the plasma in contact with the vessel walls by a vital molecular force (zoosmosis) into the tissues. VI. It is possible that platelets are aggregations of the bioplasm of blood plasma.

Argument.—Before reviewing in detail the points involved in this statement I will point out that *a priori* it seems unreasonable with our present knowledge of the bacterial cause of disease to suppose that we have permeating our tissues a helpless dead nutrient material liable at any moment to come into contact with antagonistic organisms.

I. The mere size of plasmacules presents no difficulties. Professor Michael Foster points out that protoplasma must be divided ultimately into very small particles (somacules) possessing all the properties of the whole except that of reproduction. In accordance with this plasmacular theory we find that plasma is treated with the greatest delicacy; it is enclosed in tubes of exquisite smoothness and the slightest rough handling, even contact with any solid except the vessel walls, brings about its disintegration. Again, the composition of plasma varies between definite narrow limits. Whatever food be ingested the blood plasma even in the portal vein remains of nearly constant composition. Water injected into the veins soon leaves the blood and remains in the areolar tissues until the blood can get rid of its own water and re-absorb that in the areolar tissue. In starvation though most of the tissues dwindle away the blood remains normal in composition. These facts strongly point to the view that the essential elements of the plasma are capable of maintaining their own integrity and that the plasma is not merely a solution of nutrient material.

II. There is a property of living matter which although in view of the microbic theory of disease must stand in the very first rank has not yet, I believe, received a name. It is indicated by the fact that arrangements of matter when alive remain nearly unchanged but after death go through definite changes and then disintegrate, becoming a prey to living organisms which were powerless against them when alive. I propose to call this property "vital molecular inertia." For our purpose the most important point to dwell upon is the definite change which takes place in bodies just after death before actual disintegration takes place. In muscles this is illustrated by the process of death stiffening.

Everyone reading an account of coagulation must be struck by the analogy between coagulation and death stiffening, each seems due to the death of a living substance. At every turn also we feel the want of some additional factor to explain coagulation. This factor I maintain is vitality of the plasma. According to this view, coagulation due to the action of ferment upon blood plasma happens only when the vitality of the ferment is in excess of that of plasma. I shall not go through the various intricate facts recorded as to the coagulation but only point out that upon this supposition an explanation is found for the following facts as yet not accounted for. Ferment injected into healthy blood does not cause coagulation. The injection of various substances into the blood in some cases causes coagulation and in others prevents it.

Assuming plasma to possess vital properties, these substances will have their effect in favouring or retarding coagulation according to their relative actions upon the vitality of the plasma and the ferment. The fact that blood can be kept indefinitely in tubes formed of blood-vessels is quite in accordance with the retention of vitality by blood plasma. The products of coagulation, fibrin, globulin, &c., should not be regarded as constituents of blood plasma, but merely the débris left after coagulation has been effected. "Absorption" as carried on by living tissue includes a process analogous to physical absorption and diffusion; living things suck in matter from other bodies and pass it on through their own substance. I propose to call the vital process in question "zoosmosis"; it is independent of diffusion and acts indifferently upon colloids and crystalloids. In general the process tends to equalise the distribution of the materials it acts upon, but sometimes it has the opposite effect, heaping them up in particular parts. This power is hinted at by Professor Michael Foster when he says: "The passage of material through the pores of a living cell takes place according to laws quite different from those of ordinary diffusion." It is the cause of the never-ceasing interstitial currents of fluid through every part of living matter alluded to by Dr. Lionel Beale. This well-known function of living matter has, I think, not been sufficiently invoked to explain physiological and pathological phenomena. The remarkable power of absorption shown by lymph and blood points to the possession of the power of zoosmosis by these fluids, though it is difficult actually to prove this.

Another property of living matter not much studied might be called "vital contact-attraction." It has its analogies in the physical properties called "capillary attraction" and "cohesion." It is indicated by the facts that when bodies are in contact with certain others a force is necessary to separate them and if parts of these bodies be in contact there is a tendency for them to increase the contact as much as possible. So far as our subject is concerned the important fact in relation to vitality is that living bodies vary in this respect according to their condition. To this force is due the separation of the red corpuscles in the normal blood. Normally there is an attraction between the plasma and the corpuscles maintaining the greatest amount of contact between them—that is, the separation of the corpuscles from one another. The force ceases as the blood dies and so the corpuscles fall into rouleaux. Again, there is a contact-attraction between the healthy plasma and the healthy vessel wall shown by the way in which the plasma clings to the latter. This contact-attraction enables the plasma to permeate the vessel wall but still keeps in contact with it even against pressure. In parenthesis the pressure in the capillaries cannot be very great. This attraction diminishes as the vitality of the plasma fails and deteriorated plasma leaves the vessels and flows into the lymphatic. This view is in accordance with the fact that albumose which injected

[1] A paper read before the Hunterian Society on Nov. 23rd, 1898.

Digitized by Google

into the veins causes increased flow of lymph also causes coagulation of plasma in the blood-vessels.

III. *Statement.*—Peptones, sugar, and emulsified fat are passed from the intestines by zoosmosis to the cells of the retiform tissue. These assimilate the peptones and a proportionate amount of the sugar and fat. The outer part of the cells is shed, forming plasma which passes into the blood-vessels. The excess of sugar is carried away by the portal vein. The excess of fat is divided up into minute particles forming the molecular basis of the chyle and is taken up by the lacteals. This act of metabolism is accompanied by production of waste products which give rise to an increase of urea in the urine.

Argument.—The distribution and structure of the recticular tissue of the mucous membrane of the intestines is exactly adapted to carry out the process described above. Professor Michael Foster gives the following description of a solitary gland in his Physiology, part ii., p. 516: "A solitary follicle, then, may be considered, in the first place, of a rounded capillary network fed and drained by small arteries and veins, all supported by a minimum amount of ordinary connective tissue. In the second place, the interstices of this vascular network are filled up with adenoid tissue the fine meshes of which are crowded with leucocytes of variable, but on the whole small, size. Lastly, the rounded mass thus constituted is surrounded by a lymph-sinus the fluid of which on the one hand bathes the mass and on the other hand is free to pass away into the neighbouring lymphatic canals." Furthermore, the adenoid cells are described as pushing processes between the epithelioid cells. In accordance with this view the adenoid cells show signs of great activity during digestion; some are found to be larger than others, as if the cells increase up to a certain size and then shed the outer part. Again, we have the fact that all the peptones disappear and a large part of the fats cannot be accounted for by what is found to pass by the lacteals. What is the most natural conclusion to come to? Surely it is that the missing food-stuffs have been assimilated by cells of some description. How otherwise are we to account for the disappearance of the peptones and a part of the fat and their transformation into plasma? I do not think the word "absorption" expresses the process in question; it is one of assimilation rather. If my view is correct surely the cells most likely to carry out such a process are the adenoid cells, for we know that this type of cell possesses the power of assimilation in a marked degree; they are placed in exactly the spot to effect this end and display great activity during digestion. Even if we look upon plasma as a secretion assimilation of the food-stuffs must precede the secretion. It does seem strange that it has never been suggested that the assimilative power of the recticular cells takes a part in transforming digested food-stuffs into plasma. Professor Michael Foster comes very near to this view in the following passage: "At the same time, bearing in mind that leucocytes or cells resembling leucocytes, many of them possessing in the number and nature of their granules or in other respects marked features, are found in the reticulum of the villi, we may be prepared to admit when fuller knowledge comes to us that these cells play some important part in the process of 'absorption' on which we have been dwelling." Both Professor Michael Foster's book and Professor Schäfer's agree that a profound change takes place in digested food-stuffs as they pass through the mucous membrane, but both are inclined to regard the epithelioid cells as the active agent and the vessel walls to a less extent. According to my theory there is no difficulty in explaining the large increase of urea found in the urine during digestion.

IV. Although difficult to prove many things point to the opinion that the lymphatic glands exercise a restorative action upon the lymph flowing through them. Lymph as it enters the lymphatic is, there is little doubt, plasma deteriorated in some way or other. These glands are so constructed that the lymph comes into contact with the adenoid cells analogous with those in the recticular tissue of the intestines and displaying a like activity. The renewal of lymph by the former and the production of plasma by the latter must I think be accepted or rejected together.

Statement.—The lymphocyte white corpuscles are as it were outposts of the lymphatic glands ready to assimilate deteriorated plasma.

Argument.—The presence of these omnivorous bodies scattered through the plasma is, I think, one of the best reasons for believing that plasma is alive. If it is only a nutrient fluid why do not the white corpuscles multiply indefinitely by assimilating the plasma? If now we regard plasma as budded off from the adenoid cells it would in the healthy states have the same vital molecular inertia as the corpuscles and so be able to hold its own against them. When, however, its vitality is impaired it becomes a prey to the corpuscles which first assimilate it and then perhaps shed off healthy plasma. Professor Michael Foster says: "The former (white corpuscles) probably exert a considerable influence on the blood plasma itself and help to maintain it in proper condition."

V. The question of the passage of nutrient material from the blood-vessels to the tissues is of the utmost importance and has lately been brought into prominence by Sir William Broadbent at Edinburgh when he expressed an opinion that grave disturbances of nutrition such as occurs in epilepsy and insanity may be accounted for by alteration in blood-pressure causing starvation of the tissues of the brain. In Professor Schäfer's book a complete explanation is claimed in the action of osmosis and infiltration. In it points of osmosis and infiltration are strained to the utmost if actual fallacies do not appear. Osmosis in relation to colloids sounds very much like a physical paradox. When we have to do with living tissues why should we not seek the cause of processes occurring in them amongst the vital functions which they are known to possess. The absorption of nutrient stuffs from the bowel has been clearly proved to be unexplainable by physical forces; then why should we confine our attention to these forces in studying the other end of the question—the entry into the tissues from the blood of nutrient material? When a function so important as the nourishment of the tissues is concerned we should expect it to be carried on by a process which cannot, except in extreme circumstances, be disturbed. We find this, I believe, in what I have ventured to call zoosmosis.

Statement.—When a deficit of nutrient material occurs in the tissues formed material from the plasma in the blood-vessels is immediately passed into the tissues by zoosmosis, the plasma deficient in formed material passes on giving way to normal plasma, and the process is repeated. The more quickly the deficit in the tissues is produced—that is, the greater the activity of the tissue—the greater will be the need of normal plasma to supply the want; in other words, a dilatation of the capillaries and quicker flow of plasma will be necessary. The normal formed material mentioned includes a due amount of oxygen.

Argument.—I think all observed phenomena agree with this view. It is proved that activity of the tissues is independent of the flow of lymph into the lymphatics—indeed, to get lymph experimentally from the lymphatics of a muscle put into movement it is necessary to knead the muscle. Then again, a large range of blood-pressure is compatible with good functional activity of the tissues. The possession by the capillary wall, the tissues, and the plasma of the power of zoosmosis at once explains the absorption by the blood of foreign substances and waste products against pressure.

VI. It is natural to ask what microscopic evidence have we of the presence of living substance in the plasma. It seems likely that blood platelets supply this. They take staining materials which usually stain living parts of the tissues. If the blood is removed and then an attempt is made to stain it the platelets do not appear, but if the blood is received directly into the staining fluid—that is, before the blood has had time to disintegrate—they are obtained in abundance.

In conclusion, I must apologise for having gone over so much ground, most of it rather difficult travelling; my justification lies in the fact that the questions here discussed hang together in a way which makes it impossible to consider them separately.

Victoria-square, S.W.

MANCHESTER EAR HOSPITAL.—The annual meeting was held on Dec. 6th in the town-hall under the presidency of the Lord Mayor. The total number of attendances on patients had been 10,708, as against 9507 last year. There had been 2289 new patients, as against 1990 last year, and the in-patients were 173, as against 128. Careful inquiries were made by the District Provident Society into the circumstances of the patients in order to prevent abuse of the charity.

A CASE OF SPINA BIFIDA OCCULTA.

BY P. MACLULICH, M.B. DUB.

I VENTURE to publish the following case as I believe that it will be of interest as illustrating a somewhat rare condition of spina bifida—namely, spina bifida occulta—and at the same time presenting some special features of its own. Cases of spina bifida occulta have been described by Virchow, Bland Sutton, and others, the essential feature of this deformity being the presence of all the conditions necessary to spina bifida, with the exception that the site is marked by a depression instead of a tumour, in which the skin, membranes, and cord are blended together. On looking up the records of the different cases which come under the common title of "spina bifida" I find that it is stated that over 50 per cent. occur in the lumbo-sacral region and 17 per cent. in the sacral region, while the remainder are found in the cervical and dorsal regions, the latter being the position of least occurrence. The following are brief notes of the case.

On Nov. 5th, 1898, I attended a big, healthy country-woman, thirty-five years of age, in her eighth confinement. I found the right foot presenting and delivered the child, a full-time female weighing slightly over 7 lb., with little difficulty. The mother stated that her previous labours had all been normal and were all head presentations. On subsequently examining the child's back the following conditions were found. Extending from the fourth dorsal vertebra downwards to the second lumbar was a depression covered by a thin, glistening, bluish membrane and having at its upper angle a fistulous opening about 4 mm. in diameter which passed upwards and slightly forward. There was no growth of hair over the depression or around its borders which is the usual occurrence in these cases, neither was there any hydrocephalus present, but, on the contrary, the different bones forming the cranial vault overlapped one another considerably, nor was there any deformity of the feet such as equino-varus which is frequently a concomitant of spina bifida. After birth the child made feeble attempts to suck and she soon developed cervical opisthotonos, tonic contractions of the arms, and paralysis of the legs, gradually sinking until she died on the fifth day after birth.

At the post-mortem examination, in which I was kindly assisted by Dr. Hinnell and Dr. H. Moorhead, the following interesting conditions were found. There was arrest of development of all the laminæ of the vertebral column, except that of the axis, this defect being most marked in the lumbar region, due I should think to the fact that the laminæ unite in order from above downwards. Also from the fourth dorsal vertebra upwards the neural arches posteriorly were replaced by a dense fibrous band; this was entirely absent over the region of the external visible spina bifida, but on further dissection was found to reappear at the level of the second lumbar vertebra and to be continued downwards from this point. The fistulous tract previously mentioned ran in an upward and forward direction and a bristle could be passed up this into the central canal of the cord. On examining the cranium it was seen that there was no posterior fontanelle and only a very small anterior one; this was caused by the various bones overriding one another considerably and being very firmly united so by dense fibrous tissue. The following were the relative positions of the bones of the cranium. The occipital overlapped the two parietals; the right parietal the left; the left portion of the frontal the left parietal, while the right half of the former was overlapped by the right parietal; also the metopic suture was well marked owing to the fact that the left half of the frontal was overridden by the right half. The vertebral column, as a whole, was rigid and it presented well developed curves the exact opposite to those seen in an adult—i.e., the dorsal curvature was convex forwards while the cervical and lumbar curves were convex backwards. Nothing else abnormal could be detected, except that the eyes were very deeply sunken in the orbital sockets.

The points of interest in the case are: (1) the non-union of the laminæ of practically the whole vertebral column; (2) the discrepancy between the extent of the apparent spina bifida and that which the necropsy revealed; (3) the presence of a fistulous opening leading into the central canal of the cord; and (4) the absence of other deformities and the tuft of hair which are usually described as occurring in these cases. I may mention as further points of interest that the patient's seventh child, who only lived a few days, had double hare-lip and a cleft palate and that her only relative who has ever had any congenital deformity is a nephew, three years old, who suffers from double talipes equino-varus.

Bury St. Edmunds.

A CASE OF TUMOUR OF THE ŒSOPHAGUS; TRACHEOTOMY; NECROPSY.

BY E. WHARMBY BATTLE, M.R.C.S. ENG., L.R.C.P. LOND.,

JUNIOR HOUSE SURGEON, WARRINGTON INFIRMARY; LATE HOUSE SURGEON, MANCHESTER ROYAL INFIRMARY.

I AM indebted to the kindness of Dr. E. A. Fox for permission to record the following case.

The patient was a man, aged thirty-nine years. His wife stated that at the end of March, 1897, he began to experience difficulty in swallowing. He continued well, however, until the middle of August when complaints were made of epigastric pain and "tightness of the chest." At this time a little solid food could be taken and though evidently ill he continued to work until August 29th. On this day he was seized with urgent dyspnœa and remained in bed until his admission to the Warrington Infirmary on Sept. 4th. In spite of increasing dysphagia no loss of weight had been noticed. The patient corroborated the above statement, adding that he felt perfectly well except for the difficulty in swallowing and the shortness of breath. He gave a history of alcoholism but not of syphilis. When seen a few minutes after admission the patient was sitting up in bed leaning forward. The respirations were extremely laboured and 28 per minute. There was loud inspiratory and expiratory stridor of equal intensity and duration. He explained the difficulty to be "breathing out," this pointing to the larynx as the seat of obstruction. The voice, quite clear and distinct, in no way, he said, differed from the usual. There was a troublesome short dry cough. On hearing the patient speak one got the impression of the voice being delayed, or rather of its succeeding the apparent effort to articulate. Speaking was painless but necessitated an increased expiratory effort. The face and hands were slightly cyanosed. The pupils were normal. There was no laryngeal movement during respiration and except for slight puffiness above the left clavicle the neck was normal. The chest was emphysematous and yielded no information beyond the fact that there was an equally free entrance of air to both lungs. There was granular pharyngitis, but laryngoscopically nothing abnormal was noted, both cords moving well. The pulse was 120 per minute and the temperature was 99° F. The dysphagia was extreme. On Sept. 5th the larynx was again examined and both cords were seen to move well. There was a suspicion of "brassiness" about the cough. During the morning there was an attack of severe dyspnœa lasting a few minutes. In the afternoon several such attacks occurred, becoming more prolonged and causing much distress and anxiety to the patient. During the attacks breathing was very rapid and cyanosis was more marked, but once they were over the patient lapsed into his previous condition of laboured respiration. Towards evening the cough became troublesome and morphia (¼ gr.) was given to relieve this symptom. Rectal feeding had been commenced in the morning, nothing but a little ice-water being taken by the mouth. The temperature was normal and the pulse and respirations were 130 and 27 respectively. On the 6th the patient had passed a comfortable night, sleeping four hours. Towards noon the respiration became more laboured and the cough more "brassy." Laryngoscopy was impossible. Tracheotomy was decided on with the idea of relieving the laryngeal symptoms which were now distressingly frequent. Under chloroform the operation was performed at 4 P.M. by Mr. E. E. Bowden. No difficulty was experienced in getting into the trachea and the effects of the operation were rapidly recovered from. The laryngeal spasms were relieved; respiration still continued laboured, rising by midnight to 45. The patient lived twenty hours after the operation, dying apparently from cardiac failure.

At the necropsy the heart was found to be enlarged and

Digitized by Google

flabby; the cavities, especially the right, were dilated. On the anterior wall of the œsophagus opposite the bifurcation of the trachea was an oval-shaped ulcer of the size of a florin. The centre was depressed and ulcerated; the margin was raised, indurated, and nodular. This proved to be epitheliomatous. Growing from the anterior wall above this and separated by an inch of healthy mucous membrane was a whitish globular tumour of the size and shape of a hen's egg. Over this protrusion into its lumen the œsophagus was tightly stretched, the bulging at this spot appearing before the tube was opened as if some body—as an egg, say—had lodged there. The mucous membrane of the anterior wall passed without interruption over the growth. It seemed almost impossible for even liquids to have passed this obstruction. The growth also involved the posterior wall of the trachea, projecting into its lumen as a nodular mass 1 in. above the bifurcation. The obstruction here was considerable, equal to two-thirds the calibre of the tube. The egg-shaped growth when cut into showed patches of softening. Microscopically the cells were identical with those of the ulcer. There was a large amount of small cell infiltration around the vessels. This growth also spread laterally, involving the apex of the right lung. This had the microscopical features of the tumour in the œsophagus. The left recurrent laryngeal nerve lost itself about the middle of the neck in an enlarged and probably infected gland. Unfortunately this escaped examination. The right nerve was quite normal.

Warrington.

SYMPTOMS OF POISONING FROM A SMALL DOSE OF TINCTURE OF CANNABIS INDICA.

BY ANTONY ROCHE, M.R.C.P. IREL.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND PUBLIC HEALTH, CATHOLIC UNIVERSITY MEDICAL SCHOOL, DUBLIN; EXAMINER IN THE ROYAL UNIVERSITY OF IRELAND.

IT is well known that different samples of the tincture of Indian hemp vary much in strength and also that many people are unduly susceptible to the action of the drug. In the following case the amount ordered was 12 minims every fourth hour till the pain complained of was relieved. The symptoms of poisoning showed themselves shortly after the second dose had been taken. The druggist who compounded the mixture assured me that no mistake had occurred and I took a dose of the mixture myself without any results—not a prudent course to follow, as has been more than once demonstrated.

In June, 1897, I saw a patient, aged thirty-three years, who complained much of an attack of migraine. She had at different times tried various methods of treatment without much benefit in alleviating the attack. I ordered her a mixture containing 10 gr. of strontium bromide and 12 minims of the tincture of Indian hemp in each dose, one to be taken every fourth hour till the pain was relieved or until four doses had been taken. After the first dose she felt much better and went out to make some purchases. On returning, about four hours after taking the first dose she took a second dose; within a few minutes she felt a strange feeling and an inclination to jump down the stairs. This she knew was absurd, so she clung to the bannister; she then went into her room and to bed, when I was sent for. I found her in bed in an excited, joyous state, quite conscious but, as she said herself, unable to control herself; she talked incessantly and assured me that she had such a good story to tell me, &c. Her eyes were brilliant and the pupils were slightly dilated but they reacted to light; her pulse was full and soft. She mentioned that she had a creeping sensation in her arms and legs. As it was more than an hour since she had swallowed the medicine and the symptoms were not urgent I did not administer an emetic but gave her some strong black coffee and assured her that she would be quite well in a short time. In about half an hour she became quiet and she then slept for an hour, on awaking being quite herself.

The case is perhaps worth recording. I find that Taylor mentions a case recorded by Mr. J. Roche Lynch[1] where the symptoms of poisoning were marked after a dose of 7 minims and Dr. John Attlee[2] has reported a case in a boy, aged twelve years, from a dose of 10 minims.

Dublin.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE RÔLE OF SYPHILIS IN THE ETIOLOGY OF SIMPLE ULCER OF THE STOMACH.

BY W. A. MACKAY, M.D., F.R.C.S. EDIN.

IN English medical literature syphilis is not given a very prominent place as a factor in gastric ulcer. Yet ulceration occurring anywhere else is looked upon with so much suspicion that specific remedies are almost invariably tried in doubtful or rebellious cases. Why not also in gastric ulcer? It would almost appear as if the ancient demon still presided at the cardiac orifice. Fournier cites the following cases. Case 1. About thirty years ago a young girl, a public singer, was treated for syphilitic rupia and was rapidly cured. Ten years later Fournier found this patient nearly moribund and at her side a basin well filled with blood. For more than three months she had been vomiting blood at intervals notwithstanding the administration of the usual remedies. Fournier prescribed iodide of potassium. He remarks that the cure was so rapid as to be quite theatrical in effect. Six years later this patient again presented herself in a critical condition suffering from hæmatemesis. She stated that she had returned from Italy, where on the onset of symptoms she had asked for the iodide, but her medical man refused it as being a dangerous drug in hæmatemesis. Fournier again prescribed the iodide and describes the effect as being little short of a resurrection. Case 2. A Russian suffered severely from syphilis, later he was attacked by hæmatemesis which gave way to specific treatment. Leaving off treatment this man suffered from rupia and hæmatemesis alternating, both of which readily yielded to treatment. It may be objected that these cases were markedly syphilitic and diagnosis and treatment appear easy and rational. I shall, however, now give an account of two more cases in which the history was not so clear and yet the treatment was equally satisfactory.

CASE 1.—A youth, aged fifteen years, was seized with pain and swelling of the ankle. Tuberculous disease was suspected and for this the patient was treated for some weeks. I then saw him and, recollecting that I had treated successfully his mother some time before for specific disease of the nose (the only manifestation she ever showed), I put the youth on blue pill and iodide. The joint recovered rapidly and completely. Ten years later this youth began to vomit blood and got steadily worse, although dieted carefully and given the usual remedies. Recollecting his former illness mercury and iodide were given with immediate good effect. I lost sight of this patient for three years. Meanwhile he married. His wife had an abortion at the third month and now he himself is under treatment for general paralysis of the insane which is temporarily benefited by the iodide.

CASE 2.—A man, aged twenty-four years, in a condition of complete collapse from loss of blood and fear of further vomiting, was put on mercury and iodide of potassium as a last resort although there was no history obtainable of syphilis. Within forty-eight hours improvement was marked. The treatment was continued and the patient completely regained his health.

It appears to me to be an extremely interesting fact in this connexion that bichromate of potash, introduced some years ago by Professor Frazer of Edinburgh and found so useful in cases of indigestion accompanied by pain, should prove to be the very drug which a century before in Spain and France was considered almost equal to mercury in the treatment of syphilis.

Huelva, Spain.

NOTE ON A CASE OF ACUTE INVERSION OF THE UTERUS.

BY C. HASLEWOOD, M.B., C.M. ABERD.

SUCH a case as the following is fortunately seldom seen in general practice and as the facts point to undue interference by a midwife it may be of interest to bring it to the notice of the readers of THE LANCET.

On Sept. 25th, 1898, I was called by a man to see his wife, a delicate, anæmic woman, aged twenty-four years, who had been attended in her third confinement by a midwife. But the midwife "could not manage" as "the afterbirth was fast." On my arrival about an hour after the birth of a female child I was met by the midwife who remarked that she had, "after several unsuccessful attempts, managed to get it away." Finding the patient in an alarming state of collapse I turned down the bedclothes and found the uterus inverted and prolapsed, lying between the patient's legs, with the placenta still partially adherent to the fundus. There had evidently been very considerable hæmorrhage and the radial pulse was almost imperceptible. After douching the part with a weak solution of biniodide of mercury I tried to reduce the inverted uterus and failing at the first attempt to do so I detached the placenta and tried again but without success. Not caring to administer an anæsthetic alone I was content with returning the inverted uterus within the vulva and after sending for assistance I proceeded to revive the patient who was well-nigh moribund. Mr. Hawkins-Ambler arrived later and with the patient under an anæsthetic reduced the inverted uterus, but not without considerable difficulty. Ether was the anæsthetic employed and the patient not only bore it well but seemed to be greatly benefited by it. The subsequent history is unimportant as the patient made an uninterrupted recovery and early in November was going about as usual.

Prescot.

TWO CASES OF WHOOPING-COUGH TREATED BY AURAL MEDICATION.

BY S. GLANVILLE MORRIS, M.D. EDIN.

THE following two cases were treated according to the method recently advanced by Dr. G. A. Stephens in the columns of THE LANCET.[1]

CASE 1.—The patient was a boy, aged five years. He had been suffering from whooping-cough for one week. There was a discharge from both ears, very considerable from the left one. The face was puffy. He vomited with the cough and passed very bad nights. I syringed his ears with warm boric lotion and painted the meatus and membrana tympani in accordance with Dr. Arbour Stephens's method. The first night of the treatment the child slept well; the vomiting ceased and the child has not whooped since. Pharyngitis, however, still was present, which caused cough, but on the fourth day the pharyngitis had greatly improved and the cough ceased. By the fifth day the child appeared to be well.

CASE 2.—The patient was a boy, aged six years. He had suffered from whooping-cough for one week. The appetite was poor, there was vomiting with the cough, but no pain or discharge from the ears. The ears were syringed and painted. On the next day there was no improvement. The treatment was continued. On the third night the child slept much better and whooped less, while the appetite improved. By the fifth day the child was well.

Nantgaredig, Carmarthen.

[1] THE LANCET, Dec. 3rd, 1898.

ROYAL ALBERT HOSPITAL, DEVONPORT.—The thirty-fifth annual meeting of this hospital was held on Dec. 16th under the presidency of Sir John Jackson. The report showed that during the year 581 in-patients had been admitted, as against 588 in the preceding twelve months. There were 1950 cases treated in the casualty department and there were 2826 members belonging to the Provident Dispensary. The financial statement showed that the expenditure for the year had been £4248 and that the balance had been increased from £305 to £487.

ST. MARY'S HOSPITAL FOR CHILDREN, PLAISTOW, E.

A CASE OF PANCREATIC CYST TREATED BY INCISION AND DRAINAGE; RECOVERY.

(Under the care of Dr. ERNEST B. RANDALL.)

IT is impossible to be perfectly certain that the cyst described in the following case was derived from the pancreas, but that is the most probable origin which can be assigned to it. The history of traumatism in this case is not very exact, but injury is a fairly common cause of cysts of this organ. Leith[1] has collected 17 instances and it is probable that they commence as hæmatomata. The sudden onset of acute symptoms no doubt points to the time when the contents of the cyst became septic. The operation was much simplified by the adhesions which had formed between the wall of the cyst and the anterior abdominal wall. Lately there has been a tendency to open pancreatic cysts by a posterior incision at the outer border of the left erector spinæ muscle and much is to be said in favour of this operation; but, of course, it is not advisable in a case where extensive adhesions have formed anteriorly.

A boy, aged fourteen years, was admitted to St. Mary's Hospital, Plaistow, on August 15th, 1898, suffering from abdominal pain. The patient had never in his life been ill until three months previously when he suffered for a fortnight from abdominal pain, feverishness, and sickness and was kept in bed and poulticed; since then he had been fairly well until his present illness, but his friends said that he had been getting thinner. On close questioning a history of a kick by a horse in the back a year previously was elicited, but the boy was not much injured and did not stay in bed. On August 13th he was taken ill with pain in the abdomen, sickness, and slight diarrhœa; on the 14th these symptoms continued, whilst on the 15th (the day of admission) the sickness and diarrhœa ceased, but the abdominal pain continued. On admission the temperature was 100°F., the pulse was 108, and the respirations were 28. The patient was a thin child looking younger than his age; he complained of general abdominal pain. On examination of the abdomen it was found that it did not move well on respiration. A well-marked prominence occupied the epigastric and upper part of the umbilical region; this prominence appeared to be almost median, the inclination being to the left. The abdomen was slightly tender all over. A well-marked tumour was felt corresponding to the prominence seen and gave the impression of being situated immediately behind the abdominal wall; it was tense, elastic, and fluctuating and was not moveable. A well-marked thrill could be obtained and in addition it was felt to pulsate synchronously with the cardiac impulse, but the pulsation was not expansile in character. The outline as felt extended from the ensiform cartilage and costal margin to a point 1 in. below the umbilicus, a distance of 6 in., and transversely 4 in. to the left and 3¼ in. to the right of the median line, giving a transverse diameter of 7¼ in. The surface of the abdomen was dull on percussion from the ensiform cartilage to a point ½ in. below the umbilicus, a vertical dulness of 5½ in., the transverse dulness being 6 in. An area of resonance a finger's breadth in width was present immediately below the left costal margin. The spleen was not palpable and the liver dulness was not increased. The chest was normal. The pupils were median in size and equal.

On August 16th the patient had passed a restless night; the highest temperature was 101°. No urine had been passed since his admission. A soft catheter was passed and

[1] Edinburgh Medical Journal, November, 1895.

Digitized by Google

18 oz. of urine were withdrawn; it was of specific gravity 1015 and acid and contained albumin (1 per 1000) but no sugar, blood, or bile. On the 17th no further retention of urine or albuminuria had occurred. The tumour was unchanged; it was explored with a needle, ½ oz. of chocolate-coloured pus being withdrawn which showed under the microscope leucocytes with a few red blood corpuscles and crystals resembling tyrosin; no hooklets were seen. On the 24th the patient had steadily become worse, wasting rapidly; the abdominal pain was less but the tenderness continued to be present. The temperature had been raised each night, the highest recorded being 103° on the 19th, with a morning remission to 98°. There had been no further albuminuria and the stools were normal in colour. The characters of the tumour were unchanged. The boy's weight was 3 st. 3¾ lb.

An operation having been decided on A.C.E mixture was administered on a celluloid mask. An incision 2½ in. long, commencing 1½ in. below the ensiform cartilage, was made in the median line. The peritoneum was divided and the cyst wall was immediately exposed; it was found to be adherent all round to the anterior abdominal wall. Owing to adhesions it was impossible to make out how many layers of peritoneum covered the cyst but two large vessels were seen running vertically and were thought to be of omental origin. A trocar and a cannula were thrust in and fluid was withdrawn into a sterile vessel for examination; the wall was then incised and 16 oz. of chocolate-coloured pus were evacuated. The cavity was then explored with the finger and was found to extend in the direction of both loins and back over the aorta and spine in the region of the pancreas; neither diverticula nor bands were discovered. The cyst wall was about ¼ in. thick at the point of incision; a portion was excised for examination. The cyst wall was then sutured to the abdominal wall as a precautionary measure and the cavity was drained with four strips of bicyanide gauze.

On August 25th the temperature was 97°. The patient had passed a good night. No vomiting or bad symptom had occurred. The wound was dressed; there had been some penning up of discharge. The gauze was replaced by two rubber tubes. The subsequent history was uneventful, the temperature not rising above 99° and the discharge presenting no features differing from that of an abscess cavity in process of healing elsewhere. The patient was discharged from the hospital on Oct. 2nd quite healed. His weight was 4 st. 5 lb. On no occasion since August 16th was any abnormality of the urine discovered. On Dec. 1st the patient was examined. He looked fat and well. The abdominal wall showed a slight tendency to bulge over an area of about 2 in. on each side of the scar. Neither thickening nor tenderness was discovered on deep palpation.

Examination of fluid and cyst wall.—The fluid was found to consist of blood-stained pus with a few crystals resembling tyrosin. No hooklets were seen. It did not turn starch into sugar or emulsify fat. Inoculations on gelatin and agar proved sterile. Microscopical sections of the cyst wall were stained with hæmatoxylin. The sections consisted partly of fibrous tissue in several stages of growth and partly of a glandular tissue, showing tubular alveoli lined with cubical epithelium and a scanty amount of interalveolar tissue.

Remarks by Dr. RANDALL.—The term "pancreatic cyst" is perhaps open to criticism, for the deep relations of the tumour were only ascertained as far as was possible by two examining fingers inside its cavity, and although the deeper and upper part of the cyst lay just over the region of the pancreas I am not able to say whether there was structural connexion. The microscopical sections made by Mr. W. W. Farnfield showed fairly abundant acini of glandular tissue, which glandular tissue certainly strongly resembled that of the pancreas. The absence of amylolytic or emulsifying action in the fluid may well be accounted for by the free suppuration. I have to thank my colleague, Mr. Ernest A. T. Steele, for lending me his aid at the operation.

LEEDS GENERAL INFIRMARY.

A CASE OF OBSTRUCTED LABOUR; PORRO'S OPERATION; RECOVERY.

(Under the care of Mr. LAWFORD KNAGGS.)

IT would be difficult to magine a case in which Porro's operation could be more urgently required than in the one under consideration. The extreme contraction of the conjugate at the brim by itself made the prevention of future pregnancies extremely desirable; the presence of the two fibroids tended to point in the same direction; and in addition there was the intensely septic condition of the uterine contents. It can hardly be disputed that had the uterus been left septic infection would have almost certainly followed. The complete removal, therefore, of so large an absorbing surface by the same operation that fulfilled other important indications must be considered highly satisfactory. For the notes of the case we are indebted to Dr. C. H. Moorhouse, resident obstetric officer.

A woman, aged thirty-six years, was admitted to the Leeds General Infirmary on May 7th, 1898, and in the absence of Dr. Braithwaite came under the care of Mr. Lawford Knaggs. Her friends gave the following information. She had been in labour with her first child for five days and delivery had not been effected. She had first been under the care of a midwife, but subsequently two medical men, finding delivery impossible, had sent her to the infirmary. A leg had come away in the attempt at extraction. On vaginal examination the os could be reached high up in front of and above a hard rounded mass which occupied the hollow of the sacrum. A shaggy surface presented, in the centre of which the small cup-shaped acetabulum could be felt. The antero-posterior diameter at the brim was only 1½ in. There were large sloughing sores near the orifice of the vagina and the odour left on the finger was horribly offensive. On first entering the rectum the finger impinged upon the tumour which lay apparently behind the bowel, but as the upper part of the rectum was reached it passed to the left side of it. The tumour was smooth, rounded, and hard, and immoveably fixed. After emptying the bladder two smooth swellings could be felt in the abdomen. One was the pregnant uterus and the other in the right hypochondrium was solid and so freely moveable that it slipped about on the least manipulation. The patient's condition was poor, the pulse was 120, and uterine pains had been last felt as she was being driven to the infirmary. A diagnosis of impacted fibroid was made and it was clear that with a putrid fœtus the only operation that offered any prospects of saving the patient's life was the removal of the uterus with its contents. Mr. Littlewood who saw the case concurred and without delay the patient was put under ether and the abdominal surface rapidly and carefully prepared for operation.

The abdomen was opened by a median incision 12 in. long and the tissues were so thinned that with the first stroke of the knife the peritoneal cavity was opened and the uterus was slightly wounded. The uterus, together with the freely moveable tumour which proved to be a pedunculated fibroid, was lifted out of the abdomen until its progress was checked by a pedicle passing from it to a mass firmly wedged in the pelvis. With the application of greater force this mass—also a pedunculated fibroid—came away with a jerk. A large sponge was placed over the bowels and in the pouch of Douglas and a third assistant kept the lax parietes closely approximated and drawn firmly round the neck of the uterus. This viscus with its attached fibroids was held well forwards so that any escaping discharge would fall over the thighs and not over the abdomen. It was entered on its anterior surface, in part by the knife, but chiefly by the fingers, and the opening was enlarged downwards for 5 in. with scissors. The fœtus was grasped by the neck and extracted and the placenta, which was lying loose, came out with it. The uterus contracted. The hæmorrhage was trivial and there was no occasion to tighten the elastic tourniquet which had been placed in readiness round the pedicle. A serre-nœud was now applied just above the bladder which was somewhat displaced but fortunately conspicuous. The neck of the uterus was cut through 1½ in. above the wire, a pin was passed through the stump, and the exposed uterine mucous membrane was mopped with chloride of zinc solution (40 gr. to 1 oz.). The pedicle was fixed at the lower angle of the wound, the three parietal layers—viz., peritoneum, muscle, and skin—being separately attached by a few suitably placed sutures to the peritoneal covering of the cervix well below the serre-nœud. The object was to obtain a broad, firm adhesion between the abdominal wall and the pedicle and so securely protect the peritoneal cavity from contamination by discharges which would result from the sloughing of the stump. This done the sponge was removed from the abdomen and the incision was closed in the usual way in layers. Dressings were applied and the vagina was washed out with carbolic lotion. The pulse was 150 at the

Digitized by Google

close of the operation and ergotin, strychnia, and brandy had been injected during its progress.

The subsequent course was not uneventful. On May 10th, 11th, and 12th paralytic distension of the intestines and vomiting had to be energetically combated. When this was overcome the patient became troublesome and difficult to keep in bed and had delusions of a sexual character. This lasted through the 13th and 14th and then disappeared, and on the 15th a large slough came from the vagina and from that time the vaginal discharge lost its fœtor. The stump was cut away on the 25th and the next month was spent in the healing of the cavity left. By July 9th the wound had been soundly healed for a week and she left the Ida Hospital quite well.

The specimen.—The fœtus and the placenta were in a most offensive condition and much decomposed. The left lower limb was missing. The interior of the uterus was very foul and its mucous membrane was apparently gangrenous. The two fibroids were as large as cocoanuts and were attached to the body by short narrow pedicles.

Remarks by Mr. KNAGGS.—If there are various opinions as to the best way of dealing with cases of pregnancy in which delivery is rendered impossible by the presence of a removeable tumour, or with that other group in which the obstruction is permanent and the question of future pregnancies calls for consideration, there must be a general agreement as to the necessity for the removal of the uterus and its contents when the fœtus is known to be decomposing and delivery by the natural passages to be impossible. In Cæsarean section in these circumstances the fouling of the lips of the incision during extraction of the child and the immediate proximity of a highly septic surface can hardly fail to result in non-union of the uterine wound and in the establishment of a path of infection which must end in a rapidly fatal peritonitis. The case described above is a good illustration of the value of the more radical operation.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cysts in the Ventricles of the Brain.—Blackwater Fever.—Technique of Blood Films.—Pernicious Anæmia.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 20th, the President, Dr. PAYNE, being in the chair.

The PRESIDENT referred to the loss which the society had sustained by the death of Sir William Jenner who was President in 1873 and it was agreed that a letter of condolence should be sent to the members of his family.

Dr. E. F. TREVELYAN (Leeds) showed two Brains containing Cysts, the one in the third and the other in the fourth ventricle. In the first specimen the cyst, a little less than an inch in length and pear-shaped, had adapted itself to the anterior part of the third ventricle and was attached to the choroid plexus. It was of a greyish white colour and its contents were distinctly gelatinous. The symptoms had extended over six years with intermissions. In the second specimen there was a cyst in the fourth ventricle of about the size of a filbert. It lay free in the cavity of the ventricle. Death occurred suddenly after twenty-four hours of coma. Both these specimens were looked upon as examples of hydatid disease, but the examination of the first-named had not yet been completed. No evidence of parasitic disease was found elsewhere in the body in either case. Cysts in the ventricles of the brain might be parasitic in origin or be simple cysts of the choroid plexus. Parasitic cysts whether due to the echinococcus or cysticercus cellulosæ might lie free in the cavity of the ventricles or be attached. A single cyst of the choroid plexus, especially if of large size, should always be carefully examined as to its nature to see that it was not parasitic. Dr. Trevelyan also showed a Brain with Two Tumours at the Base; the one lay just below the velum interpositum and above the corpora quadrigemina which it had flattened out and the other in the floor of the third ventricle just above the optic commissure. He called it provisionally an angio-myxo-sarcoma.

Mr. W. H. CROSSE and Mr. W. C. C. PAKES communicated a paper on Blackwater Fever. A young officer who had served for fourteen months in Nigeria had several attacks of malaria whilst out there and came home suffering from his third attack of dysentery. He never had blackwater fever in Nigeria, but was attacked for the first time in England. The attack began apparently as an ordinary one of malaria, but after two days the symptoms of blackwater fever supervened. He had considerable pyrexia, was jaundiced, vomited green matter, and passed porter-like urine. The urine contained a fair quantity of albumin but only a few red discs. He had no quinine until six hours after the onset of the hæmoglobinuria. In spite of his improving under quinine he had a slight relapse of the hæmoglobinuria which disappeared whilst he was having still larger doses of quinine. The urine three days after the onset of hæmoglobinuria was pink in colour, gave a band of hæmoglobin, but not of urobilin. Sugar and bile pigments were both absent. Albumin was present to the extent of rather more than 1 part in 1000. There was an increase in the leucocytes and a considerable number of granular casts and renal cells. Only a very few red discs were present. Hæmatozoa were found in the peripheral blood; these, Mr. Crosse and Mr. Pakes thought, resembled the æstivo-autumnal parasite and not the ordinary quartan or tertian parasites. After the relapse the blood and urine were both again examined. No hæmatozoa could be found; there was a definite leucocytosis; and nucleated red discs were seen. The urine was similar to the previous specimen, but the casts and renal cells were much fewer. They thought this case had an important bearing upon the causation of the disease. Three alternatives appeared to be open. Firstly, that blackwater fever was unconnected with malaria or quinine; secondly, that it was caused by quinine; and thirdly, that it was connected with malaria. If the first alternative were true it would follow that the disease could be acquired in England or must have a latent period of over a month, since the patient had left Africa more than a month previously. Neither of these, they thought, was borne out in fact. That this case could not have been caused by quinine they were satisfied because, as had been stated, the blackwater preceded the administration of quinine by six hours. That the disease was connected with malaria was supported by the fact that hæmatozoa were found by them and had been found by other observers, notably by Plehn who considered that those found in blackwater fever differed in nothing from those found in the ordinary tropical African malaria. Further, the disease was only found to attack those resident in, or having resided in, tropical countries. Blackwater fever did not attack people who had not previously suffered from malaria. There appeared to them to be two alternatives as to the causation. In the first place there might be a special hæmatozoon which was responsible for the disease. Texas cattle fever was caused by a hæmatozoon and severe cases were marked by hæmoglobinuria. On the other hand Plehn's statement contradicted this idea. They thought that the most probable theory was that the hæmoglobinuric fever was really a complication of tropical African malaria, having similar relation to that disease which hyperpyrexia had to rheumatic fever. As in rheumatic fever, the hyperpyrexia was an added symptom which was unaffected by salicylates or alkalies, so the blackwater complication was superimposed upon malaria and required additional treatment. They referred to the notes on a case of blackwater fever published in THE LANCET of Dec. 3rd by Mr. F. P. Mackie. They did not consider the notes at all satisfactory. He had found parasites in stained films but had been unable to demonstrate them in fresh specimens. He noted the presence of an increase in the extra-corpuscular flagellated bodies in a mixture of blood and normal saline after two days and although he was unable to obtain permanent specimens of them was convinced that they could not be bacilli; Mr. Crosse and Mr. Pakes did not think that he had proved this. They pointed out that blastomycetes which were not saccharomycetes were quite common in the urine after exposure to the air. They pointed out the uniqueness of Mr. Mackie's case in that he demonstrated granular casts in a urine containing no albumin.—Dr. WASHBOURN said that the characteristic feature of blackwater fever seemed to be the presence of hæmoglobin in the urine, but the fact that there were also blood-cells present suggested that there was in this disease some further change in the kidney which allowed blood-cells to pass. He was of opinion that the disease was due to malaria and not to a different hæmatozoon, since the disease only occurred

Digitized by Google

in subjects who had previously suffered from malaria, and as in the pernicious form of malaria the parasites may fix on certain organs—for instance, the capillaries of the brain—and give rise to a condition simulating apoplexy, or the capillaries of the intestine may be attacked giving rise to a condition similar to cholera, so it was possible that the parasite might in this form of fever fix on the kidney and red marrow and produce the hæmoglobinuria. The fact that only a few parasites were found rather pointed to the fact that they were situated in one part of the body and did not become generalised.—Dr. ROLLESTON suggested that there was possibly some relationship between hæmoglobinuric fever associated with jaundice and the hæmoglobinuria occurring in malaria.

Mr. W. C. C. PAKES and Dr. R. HOWARD brought forward a short communication on the Technique of Blood Films. They pointed out the unsatisfactoriness of the "two cover-slip" method and showed how Dr. Manson's suggestion to make blood films with tissue paper could be adapted to cover-slips which were much more convenient than slides. They showed a special needle with which to prick the ear or finger for the collection of the blood and a clip with which to hold the cover-slips conveniently while making the films on them. They pointed out that carbol thionin blue which was recommended by Muir and Ritchie as a bacterial stain was an excellent double stain for blood, especially for the diagnosis of malaria and leucocytosis, and in tissue. They also showed a small case containing Ross's diagnostic microscope, but specially adapted without increasing its size to contain in addition all the requisites for examination of blood.

Dr. H. M. FLETCHER described an Unusual Form of Intestinal Lesion occurring in Pernicious Anæmia. The patient, a man, aged thirty-four years, was under the care of Dr. Hensley at St. Bartholomew's Hospital and presented all the clinical features of an extremely severe case of this disease. After temporary improvement he died and the appearances characteristic of the disease were found at the necropsy. Specimens of various organs were shown by Dr. Fletcher. The most interesting lesion was that found in the intestines, the whole of the colon and a small portion of the ileum being thickened, tough, and leathery and of a yellowish-brown colour. The mucous membrane showed a remarkable roughening and was covered with warty excrescences arranged in patches. Such changes in the colon have not hitherto been described as occurring in pernicious anæmia. During life there had been no symptom which bore any relation to the lesion. Microscopically there was a recent partial necrosis of the mucosa and an older fibrotic condition of the submucosa. There were intense hyperæmia and a few scattered hæmorrhages. No definite cause for these changes could be assigned. It was suggested that the older changes were probably of the same nature as those described by Hunter, Fenwick, and others as occurring in the stomach in pernicious anæmia. He negatived the idea that the condition was due to arsenic which had been taken, since the stomach and duodenum showed no change.—The PRESIDENT said that the fact that the duodenum and stomach were not affected did not negative the fact that the condition might be due to arsenic, since in antimony poisoning the effect falls altogether on the colon.—Dr. WASHBOURN instanced the action of mercury on the colon in the same connexion.

Dr. C. D. GREEN showed a specimen of Sarcoma of the Left Lung and Mediastinum from a girl, aged fourteen years, who three months before her death complained of general weakness and dyspnœa. There were physical signs over the left lung which Dr. Green associated with consolidation and contraction of the left lung consequent upon antecedent pleural effusion. Glands appeared above the right clavicle and the child emaciated with remarkable rapidity during the last days of life. At the necropsy a large malignant growth was seen to extend from the sternum to the vertebræ and from the xiphoid to the upper opening of the thorax. The arch of the aorta and great vessels was completely embedded in the growth. The left pleura was universally adherent and the left lung was seen to have been converted into a malignant mass which appeared to have grown from the hilum outwards. The growth on section proved to be a sarcoma and Dr. Green thought that it had probably originated in the glands at the hilum of the left lung.

Dr. E. F. TREVELYAN showed the following specimens:—(1) Encapsulated Growth in the Kidney; (2) Cholecystitis from a case of Typhoid Fever; (3) Calcareous Mass on the Mitral Valve; and (4) a Fibrous Tumour free in the Peritoneal Cavity.

MANCHESTER MEDICAL SOCIETY.

Renal Tuberculosis.—Tumour of the Pons.—Malignant Jaundice.—Development of Movements of the Hand in Infancy.—Peripheral Neuritis.

A MEETING of this society was held on Dec. 7th, Mr. G. A. WRIGHT, President, being in the chair.

Mr. T. JONES mentioned two cases of Renal Tuberculosis in each of which the kidney had been removed, both ending in recovery. The first case was that of a man, aged forty-three years. He had a tumour filling the left side of the abdomen. Its contour was distinct; notching of its lower margin, together with absence of anything abnormal in the urine, led to the diagnosis of a splenic tumour. Exploration by an anterior incision showed its renal origin. Removal was followed by complete recovery. The second case was that of a man, aged twenty-one years, who was admitted with a large right lumbar abscess which was opened and drained. Five weeks later, after some improvement in the patient's general condition, the diseased kidney was removed through the loin. Besides the disease in the kidney there was a large and hard tuberculous nodule in the right epididymis. The corresponding vesiculæ seminales and prostate were also diseased. The patient was shown to the meeting in the enjoyment of excellent health.

Dr. DIXON MANN described a case of Tumour of the Pons of which a minute pathological investigation had been made by Professor Delépine. The earliest symptom was a humming noise in the left ear; this continued until death which took place two and a half years afterwards. Ptosis occurred early and then disappeared; it subsequently recurred and persisted. During the later stage the patient had repeated attacks of tonic spasms and on one or two occasions epileptiform seizures. The right arm and right leg were spastically contracted and devoid of motive power. Professor Delépine found that the tumour was a round-cell sarcoma situated in the left crus; it involved all the cranial nerves excepting the first and the ninth, but the third was the only one which showed marked indications of physical changes; it was atrophied, its diameter being only two-thirds that of the corresponding nerve on the right side.

Dr. HARRIS related a case of Malignant Jaundice (Typhoid Icterus) and showed preparations from the liver of a man, aged fifty-seven years, who had died from jaundice associated with nervous symptoms and the typhoid state. The patient had been ill seven weeks before admission to the hospital and died six days after he had come under Dr. Harris's observation. The chief symptoms during the six weeks previously to his admission to hospital had been pains in the limbs and pains in the abdomen and vomiting. The jaundice had been present about eight days before admission and was extremely intense when the patient was admitted to the infirmary. Shortly after admission low muttering delirium with picking at the bed-clothes came on; the tongue was dry and brown and there were sordes on the teeth; the stools were clay-coloured; the urine contained bile and a few sheaves of tyrosin were obtained from several specimens but no leucin could be obtained. The liver dulness was slightly increased in size; there was no enlargement of the spleen. The urine contained a doubtful trace of albumin. The patient became comatose, urine and fæces were passed unconsciously, and he died about six days after admission or about eight weeks after the onset of his illness. At the post-mortem examination the body was found to be intensely jaundiced. There was no lesion in the intestinal canal, there was no obstruction at any part of the bile-ducts, and the gall-bladder contained a little dark reddish-brown bile. The liver weighed 3lb. 10 oz., was slightly more friable than usual, but showed no sign of yellow or red atrophy, and with the exception of being bile-stained presented no unusual features to the naked eye. Microscopically the liver cells were of somewhat peculiar shape, slightly cloudy, but the most obvious change was that the nuclei showed marked evidence of active proliferation and stained unusually well with logwood. The other organs of the body presented nothing unusual with the exception of being bile-stained.

Dr. ALFRED MUMFORD read a paper on Development of Movements of the Hand in Infancy. He said that limb movements might be classified as those of locomotion; of prehension, where the thumb was inactive or acted with the fingers; and of manipulation, in which the thumb acted apart from the fingers and the hand could be supinated.

Digitized by Google

Infantile movements were mainly involuntary and inherited and with these inherited movements were those of reflex action, instinctive and so-called spontaneous movements. Movements of manipulation were mainly acquired and voluntary. Independent use of the thumb with the power of supination so characteristic of manipulation began about the fifth month and was fully developed by the twelfth month. There were, however, still many inherited and instinctive movements which did not appear till later—e.g., walking. Swimming movements seemed natural to the human being and were partly at least inherited and not purely acquired movements since the human infant could be, and was, taught to swim in the very early months of life in many of the Pacific Islands, the Sandwich Isles, and in Siam. Photographs and drawings of the several movements described were shown to the meeting.

Dr. EDGE mentioned some cases of Peripheral Neuritis. Two of them were due to the use of alcohol and one to diphtheria; these were compared with three others which were caused by the toxin of beri-beri.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

THE third meeting of the session of this society was held in the library of the Royal Infirmary, Newcastle-on-Tyne, on Dec. 8th, Mr. RUTHERFORD MORISON, Vice-President, being in the chair.

Dr. A. E. MORISON showed:—1. A patient, aged twenty-two years, who had noticed a Lump at the Root of the Neck for the past two years. A skiagram proved this to be due to a cervical rib over which the subclavian artery ran. On the opposite side the transverse process was elongated. 2. A New Method of Preparing Catgut. After immersing in ether for twelve hours the catgut is wrapped upon glass and placed in a 5 per cent. solution of formalin for twenty-four hours, then under running water for twelve hours, and lastly dried. It may be kept in this condition and immediately before use boiled, or it may be kept permanently in a 1 in 2000 solution of corrosive sublimate in methylated spirit. The advantages claimed were absolute sterility and maintenance of the strength of the catgut.

Dr. G. R. MURRAY brought forward:—1. A case of Friedreich's Ataxia in a male, aged eighteen years, whose sister, aged twenty-two years, also suffering from this disease, was in the hospital under the care of Dr. Oliver. The case presented decided mental deficiency; nystagmus was very evident; the pupils, however, readily reacted to light; the usual irregular muscular contractions were present and most marked in the muscles of the face and neck; the gait was extravagantly ataxic but the knee-jerks were not absent. Dr. Oliver's case, presenting similar symptoms, was also shown to the meeting. 2. A case which Dr. Murray considered illustrated the relationship between General Paralysis and Locomotor Ataxia. This patient twelve years ago suffered from plumbism and two years ago from rheumatoid arthritis; twelve months ago he had a left-sided hemiplegia. He now presented some loss of power in the left side; speech was somewhat indistinct, and the pupils were unequal. The marked incoördination, however, was more evident on the right side. The right hip and great toe-joints showed extensive Charcot's disease.—Dr. GORDON BLACK and Mr. RUTHERFORD MORISON discussed the joint changes.

Dr. H. P. BENNETT exhibited a patient with Optic Atrophy following injury. This man, after being unconscious for one hour from a severe accident due to a fall of stone, vomited a large quantity of blood and presented marked swelling of the right eyelids. On the subsidence of the swelling there was absolute blindness of the right eye with optic atrophy and anæsthesia of the skin below the orbital margin. The explanation offered was a fractured base extending into the optic foramen and sphenoidal fissure.

Dr. PAGE reported the case of a man upon whom he had recently operated by extirpation for Arterio-venous Aneurysm in Hunter's canal. The patient eight years ago had stabbed himself by accident in the right thigh causing profuse bleeding which was arrested by a pad and elastic bandage. In a few days the wound had healed, but pulsation was at once noticed and together with swelling gradually increased. Lately increased pulsation and thrill had caused loss of sleep. On examination a pulsating and expansile swelling as large as a fist was found in the site of Hunter's canal. The thrill and bruit characteristic of arterio-venous communication were heard over the sac and along the course of the femoral vessels. There was no enlargement of the superficial veins or œdema of the foot. On Nov. 16th the sac, together with portions of both artery and vein involved, was completely removed, catgut ligatures being used. The patient made an uninterrupted recovery and at no time was there cause for anxiety as to the safety of the limb.

Mr. RUTHERFORD MORISON described his Method of Treating Fractures of the Tibia and Fibula as follows: without attempting to set, the fractured leg was put up for ten days with plenty of packing in Gooch splinting. This temporary splint was then removed and the bones and callus were moulded into shape and position. The limb was then put up in plaster-of-Paris. Two patients having been so treated showed excellent results.

Mr. ANGUS showed a patient four years after Removal of the Penis and Infected Glands which on microscopic examination had been proved to be epithelioma. There was no recurrence.—Mr. RUTHERFORD MORISON, Mr. MARTIN, and Mr. LYON SMITH commented on the improved statistics for malignant disease after radical operations.

The following specimens were exhibited:—

Dr. MODLIN: Suppurating Dermoid Cyst.

Dr. G. R. MURRAY and Mr. HARDCASTLE: (1) Stained Slides illustrating the stages of Widal's reaction for enteric fever; and (2) Case with Tubes for sending specimens for bacteriological diagnosis.

Dr. G. R. MURRAY: New Pillow Sling.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

Tuberculous Tabes.—Abdominal Section.

A MEETING of this section was held on Nov. 25th, Dr. E. H. BENNETT, the President, being in the chair.

A discussion took place on Dr. Macan's case of Tuberculous Tabes.—The PRESIDENT said that although the pus extravasated into the cavity of the peritoneum may not have had any pathogenic organisms in it, yet if it escaped from ovaries which were masses of tuberculous degeneration it was hardly to be desired that it should be left in the cavity of the peritoneum, and he therefore thought that drainage was advisable in this case.—Dr. JELLETT said it was a mistake to think that because pus was sterile there was no necessity for drainage, as pus, though sterile, might cause subsequent suppuration owing to saprophytic changes. The degree of virulence might sometimes be such as to establish suppuration without bringing on peritonitis which would kill the patient. He thought that drainage was advisable in all cases except where the patient's condition was absolutely hopeless.—Dr. H. C. TWEEDY said this case exhibited the immunity that patients who are suffering from suppurating tumours have to sepsis; in his experience, when the tumour bursts into the abdominal cavity the patient seldom gets sepsis and the fact that the pus is fœtid does not make the prognosis worse. Of course he supposed that the germs had died, but the fact that the pus was fœtid showed that germs had been there and that therefore there were dangerous toxins in the pus. He therefore thought that not to drain the abdomen would have been to run a great risk of leaving toxic pus in it.—Dr. MACAN, in replying, said that he could not understand how a piece of gauze stuffed through the posterior cul-de-sac of the vagina could drain between the intestines. He knew that pus sometimes was sterile, but investigation showed that it took about eighteen months for a tube case to become sterile.

Dr. ALFRED J. SMITH described a second series of 100 Cases of Abdominal Section, including operations performed under circumstances as follows: 39 times for ovarian tumours; 4 times for the separation of adhesions; 9 times for exploratory purposes; 21 times for the cure of fibro-myomata; once to enucleate a broad ligament fibro-myoma; 4 times for tubal pregnancies; 4 times for the radical cure of ventral herniæ; 4 times for double pyosalpinx; once for appendicitis; once for double hæmatosalpinx; once for enucleation of mesenteric cyst; once for Porro's operation; twice for salpingo-ovaritis; twice for hydrosalpinx; and once for the enucleation of a broad ligament cyst. The peritoneal

Digitized by Google

cavity was opened twice in performing anterior colpotomy and 3 times in performing posterior colpotomy. As to the treatment of fibro-myomata he was not in a position to dogmatise, but he felt it his duty not to accept the simple fact of the presence of a tumour as a sufficient indication for operation; he must be satisfied that its continued presence was in some way or other a menace to life or that its presence was incompatible with a comfortable existence. Enucleation was performed twice, myomectomy 6 times, panhysterectomy twice, retro-peritoneal hysterectomy 8 times, and double oöphorectomy 3 times, making in all 21 operations without a death. Dr. Smith also read notes of the *technique* which he employs in performing retro-peritoneal hysterectomy, and notes on the after-treatment of cases of abdominal section. Taking the first series of 50 cases and the present one of 100 he performed 150 abdominal sections with only 2 deaths, or a percentage of only 1·3 per cent. nearly.—Mr. TOBIN described how the surgeons of St. Vincent's Hospital had all arranged to operate in the same way and if a change was to be made in any details the surgical staff met together and rejected or adopted the proposed change. He thought that this was an admirable arrangement for all concerned.—The PRESIDENT and Dr. MACAN also discussed the paper and Dr. SMITH replied.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of this society was held on Dec. 15th, the President, Dr. Macfie Campbell, being in the chair.—Dr. J. E. Gemmell related a case of Sudden Death from Complete Thrombosis of the Basilar Artery occurring on the twelfth day after a normal parturition. The patient was in the Lying-in Hospital, was aged forty years, primipara, and the perineum was torn at the labour; this was repaired at once and healed by first intention. She suffered from insomnia for the first four days and the temperature reached 100° F. on the third, fifth, and seventh days; the pulse was 76. On the seventh day the nurse reported a "short fit," twitching of the muscles of the face and limbs, followed by a short period of unconsciousness. On the twelfth day the patient died suddenly whilst taking a cup of tea. Post mortem all organs were found to be healthy, but the basilar artery was completely thrombosed. There was nothing to suggest septic mischief. The uterus was 6 in. long from the cervix to the fundus. Many cases of sudden death were recorded from ten to fourteen days after labour and there being no post-mortem examination were generally put down as pulmonary thrombosis.—Mr. G. G. Hamilton showed a male child, aged three months, on whom he had operated twenty-four hours after birth for Atresia of the Rectum. Neither urine nor fæces had been passed. There were atresia of the rectum, no trace of an anus, some hypospadias, and an imperfectly developed urethra. The rectum was found high up and some days later a urethra was made. Through the urethra fæces at first came, but now the child passed urine and fæces in a natural manner.—Dr. T. R. Glynn read notes of a case of Infective Heart Disease.—Mr. Hawkins-Ambler traced the history of the procedure and the methods of using Saline Irrigation in Abdominal Operations as a hæmostatic and for the purposes of lavage. He discussed the indications for its use and avoidance. He pointed out the advantages of saline irrigation in minimising inflammatory exudations after operation and relieving that inspissation of the blood shown in its increased specific gravity which caused increased peripheral resistance and more or less circulatory embarrassment. The absorptive capacity of the peritoneum was discussed and it was contended that irrigation lessened shock by protecting the peritoneum and assisted its efforts to combat septic influences. Post-operative uses of irrigation were mentioned as a treatment in commencing peritonitis, in pseudo-ileus, and in relieving intestinal obstruction in early stages when caused by slight adhesion. A case illustrating this use was mentioned. An analysis of the use of irrigation in 30 cases of abdominal operations was presented.—Mr. Alexander used irrigation only in special cases and always used sterilised water. For hæmorrhage he would be afraid to use water hotter than 100° F. and certainly would not use water at 120° in the abdominal cavity. He preferred perchloride of iron as a hæmostatic for oozing. For shock he thought it better and safer to use saline solution injected per rectum or in extreme cases into the cellular tissue of the axilla.—Dr. Briggs considered that simple irrigation and drainage conducted with care were harmless. Lord Lister had shown in wounds the vast differences between gross and mild infection and between organisms without and within the tissues. It was not necessary to go beyond those differences in estimating the value and use of irrigation and drainage.—Professor Sherrington and Mr. E. T. Davies also spoke.

FORFARSHIRE MEDICAL ASSOCIATION.—A meeting of this society was held in the University College, Dundee, on Dec. 2nd, Dr. J. Mackie Whyte, Vice-President, being in the chair.—Dr. Whyte showed a boy, aged twelve years, who was admitted in June, 1896, to the Dundee Infirmary for ascites. He had been a delicate child and had suffered from a chronic otorrhœa—otherwise there was nothing marked till the onset of this illness six weeks previously. There was evidence of lardaceous disease in the liver, spleen, kidneys, and intestines. In the liver too there seemed to be deep fibrous constrictions. The abdomen was tapped repeatedly till October, 1897; the amount of fluid drawn off latterly was 324 oz. in nine days. The urine up to that time was very scanty, but after the tapping in October it suddenly increased in quantity and the fluid ceased to gather in the peritoneum. The cause of the disease was apparently the otorrhœa, syphilis being excluded with a fair degree of certainty.—Dr. Whyte also showed a Brain from a case of Purpura with Hæmorrhage into the Base which seemed to have begun at the optic thalamus. The patient had numerous hæmorrhages all over the body. There were no symptoms localising the cerebral hæmorrhage from which she died.—Mr. D. M. Greig showed part of a Catheter removed by Suprapubic Cystotomy from the Bladder of a man, aged sixty-three years, suffering from an enlarged prostate.—Dr. J. A. Kynoch showed a specimen of Gonorrhœal Salpingitis and Abscess of the Ovary removed by cœliotomy.—Dr. Kynoch also read a paper on the Recent Improvements in the Treatment of Vesical Fistulæ. In this paper he described the various operations suggested and performed during the last fifty years for the treatment of small, medium, and large fistulæ where there was destruction of tissue. He gave notes of a case under his own care in which he had obtained a successful result by paring and suturing the edges of the fistula. Lastly he dealt with vesico-uterine fistulæ, in the treatment of which he thought that when closure of the os uteri was the only available treatment the ovaries might be removed at a subsequent operation.—Professor MacEwan, Mr. D. M. Greig, Dr. Buist, and the Vice-President all spoke on the paper.—Dr. Kynoch briefly replied on the discussion.—Dr. MacGillivray communicated a short paper on the Treatment of Iritis in which he emphasised the importance of the early and energetic use of atropine combined with cocaine in the form of an ointment. This ointment he recommended should be applied every hour or oftener till all synechiæ were broken down. He also advocated the internal administration of mercury, hot fomentations, and leeches to the temples to allay severe pain.—Dr. A. J. Duncan spoke on the internal treatment which he did not think was sufficiently emphasised in the paper.—The Vice-President also spoke.—Dr. MacGillivray, in reply, said the paper did not aim at, though approving of, etiological treatment.

BRITISH ORTHOPÆDIC SOCIETY.—The annual general meeting of this society was held at the Westminster Hospital, S.W., on Dec. 9th.—Dr. Wohlmann, Dr. Bennett, and Dr. Melsome were elected members of the society. Mr. Freer, Mr. Robert Jones, and Mr. William Thomas were elected members of council. A vote of thanks to Mr. E. Luke Freer for his services as provincial secretary was carried unanimously.—An ordinary meeting followed at which Mr. Horrocks Openshaw's paper on Tendon Re-implantation, adjourned from the last meeting, was read. He defined the proceeding as the transference of the tendon of a healthy muscle from its normal situation and its attachment, implantation, or grafting upon the tendon of a muscle more or less completely paralysed. He gave a history of the subject and a *résumé* of cases recorded which showed that almost every tendon near the ankle had been utilised to strengthen every other muscle when paralysed, and that the sartorius had successfully been employed by Goldthwait as a substitute for the quadriceps. He had found the results of grafting the peronei into the tendo Achillis for talipes calcaneus excellent. In several cases of paralysis of the tibialis posticus he had grafted the peroneus longus or brevis into it with satisfactory results. As a general rule in tendon grafting

Digitized by Google

a muscle should be selected the action of which nearly resembled that of the paralysed one, but this was not always possible. In some cases it was advantageous to take an antagonist that was causing distortion, but care must be taken that too much was not done and an opposite deformity produced. Distortion ought previously to be removed by operation and instrumental treatment. Strict asepsis was a *sine quâ non*. The tendons should be disturbed as little as possible and as large surfaces of tendon applied to one another as possible, and they should be very firmly united by sutures that would not rapidly be absorbed. Stout catgut he considered the best material. Kangaroo tendon could hardly be sterilised by ordinary methods and silk often gave rise to stitch abscesses and troublesome sinuses.—The meeting terminated with a vote of thanks to the committee of the hospital for the use of their board-room.

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on Dec. 9th, Mr. H. Nazeby Harrington, President, being in the chair.—Dr. Temple showed two children with Congenital Defects of the Forearms and Hands.—Dr. R. Owen Morris showed a woman with Abdominal Tumour (for diagnosis).—Mr. Herbert Butcher opened a discussion by reading a paper on the Causation, Differential Diagnosis, and Treatment of Torticollis, first dealing in a thorough manner with the action of the muscles which would be involved in certain deformities and the necessity of differentiating which muscles were actually at fault in any special case, so that, a correct diagnosis having been arrived at, manipulation of the head might be employed in the proper direction and massage of the faulty muscles employed. In obstinate cases when milder measures had failed the minor operation of tenotomy was advocated and the operation recommended by Mr. Butcher was the open method in preference to the subcutaneous and in girls the high operation on the sterno-mastoid—viz., the incision being made round the auricle and the muscle divided at its insertion into the mastoid process. After tenotomy of this muscle the head should at once be placed in the correct position and retained there by a retentive apparatus and if it was found impossible to replace the head it should be forced into position during anæsthesia. In the spasmodic variety Mr. Butcher insisted that nothing seemed to avail but operation and recommended an early resection of the spinal accessory nerve at the anterior border of the sterno-mastoid muscle and even if retro-collic spasm existed no further operation should be undertaken for at least a couple of months, as in these cases the simple resection of the spinal accessory nerve had been known to result in cure. If this should not occur then the sub-occipital triangle should be exposed and the great occipital nerve with the first, second, third, and fourth nerves would come into view and one or more of them might be dealt with if necessary. Mr. Butcher quoted cases where one or more of these posterior cervical nerves had been resected with brilliant success.—The following took part in the discussion: Mr. Vacher, Mr. Laird Pearson, Mr. Dixon, Mr. Ellis Pearson, and the President.—Mr. Butcher replied.

BRISTOL MEDICO-CHIRURGICAL SOCIETY. — A meeting of this society was held in the Medical Library of University College, Bristol, on Dec. 14th, Dr. Roxburgh being in the chair.—Dr. C. Elliott showed a patient with Lichen Ruber Planus. Dr. Waldo and Dr. A. J. Harrison spoke on the subject.—Dr. Michell Clarke showed a case of Acromegaly.—Dr. E. C. Williams showed the following patients: (*a*) cases treated by the localised application of superheated dry air; (1) a case of Stiff knee; (2) a case of Rheumatoid Arthritis; and (*b*) a case of Alopecia Areata treated by the oxygen cap.—Dr. Rogers, the President, Dr. J. Swain, Mr. Paul Bush, Dr. Carey, Dr. Elliott, and Dr. Waldo remarked on the cases.—Mr. C. A. Morton showed a large Sarcoma of the Kidney successfully removed from a young child.—Mr. R. Williams and Dr. Carwardine discussed the specimen.—Dr. J. O. Symes showed a microscopic specimen of Tetanus Bacilli in Pus and a lantern slide of the same specimen.—Dr. Michell Clarke showed a microscopic specimen of the Malaria Parasite and illustrated his remarks by some carefully prepared lantern slides.—Dr. J. Swain showed a specimen of Double Pyosalpinx.—Dr. W. C. Swayne read a paper on Symphysiotomy with notes of a case.—Dr. J. G. Swayne and Mr. Morton commented on the paper.—Mr. Munro Smith showed a large number of lantern slides illustrating the pathology of Rodent Ulcer, explaining each slide as it was thrown on the screen by the oxy-hydrogen light; his interesting remarks on the subject raised a long discussion in which Mr. Morton, Mr. Williams, Dr. Edgeworth, and Dr. Michell Clarke took part.

ÆSCULAPIAN SOCIETY OF LONDON.—A meeting of this society was held on Dec. 16th, the President, Mr. D. H. Goodsall, being in the chair.—Dr. B. G. Morison read notes of a case of Appendicitis in a man, aged twenty-six years, whose symptoms were of sudden onset. At the end of the acute attack—the seventh week—Mr. A. Quarry Silcock did a lateral laparotomy when he removed the appendix containing hard, light, black concretions and stitched a peritoneal flap over the stump. Recovery was complete.—A general discussion followed.—Mr. Reginald Brown read notes of a case of Recurrent Clonic Spasm of the Abdominal Muscles in a man, aged thirty-three years, convalescent from pneumonia. In the first attack morphine checked the spasm completely in 2 days. A relapse took place in 10 days when the extensors of the thigh were involved.—Mr. Brown also showed a Larynx from a man, aged forty-five years, an alcoholic, who was suddenly affected with cough, alteration of voice, and dyspnœa, which rapidly increased as did the submaxillary swelling. Tracheotomy was done. Five hours later his pulse was 140 per minute and a few hours later he died on the beginning of the third day.—Mr. F. Hewitt Oliver showed a specimen of Red Hepatisation of the Lower Part of the Upper Lobe of the Right Lung from a boy at work on Monday, ailing on Tuesday, and dead on Wednesday.

Reviews and Notices of Books.

Orthopædic Surgery. By JAMES E. MOORE, M.D., Professor of Orthopædia and of Clinical Surgery in the College of Medicine of the University of Minnesota, &c. With 177 Illustrations. London: The Rebman Publishing Co. Philadelphia, U.S.A.: W. B. Saunders. 1898. Pp. 354. Price 14*s*.

ORTHOPÆDIC surgery is of modern origin. Attempts had been made from time to time to remedy some of the more marked deformities, but as they were made without any exact knowledge of the true pathology of the conditions which were to be remedied the attempts were nearly always utter failures. Then followed the era of the instrument-maker and the complexity of the machines which were devised to remedy deformities was only equalled by their uselessness. In more recent times a more hopeful practice has prevailed, for it has been recognised that orthopædics are only a part of general surgery, yet a part for the successful practice of which a special knowledge and a special training are required. Orthopædic departments and lectures now exist at many general hospitals and these are likely to be more beneficial than special orthopædic hospitals for students are more likely to profit by their teaching. Even nowadays too many surgeons think that they have done all that is required of them when they send an orthopædic case to an instrument maker. They themselves should provide the measurements and the details of the instrument which is to be made, and unless they can do so they should not attempt to treat these cases. We extend a cordial welcome to Dr. Moore's treatise which is before us, for it is evidently written by one who is well acquainted with the subject with which he deals. The book is written by a general surgeon who has charge of a special department, and therefore we obtain, as we might expect, a satisfactory mean between too much and too little operating in orthopædic cases. The work is clearly written, amply illustrated and excellently printed.

The exact bounds of orthopædics have never been traced and as time goes on its borders will certainly extend, but at the present time the subject may be said to include all deformities of bones and joints, and that is practically what we find in Dr. Moore's book.

Digitized by Google

The author is an enthusiastic advocate of plaster-of-Paris, and his cautions as to its quality and use are worthy of attention in this country where there appears to be a tendency to discontinue its use for spinal jackets as being not satisfactory. He advises that the very best plaster should always be employed for it sets more quickly and more firmly than the cheaper kinds; the ordinary commercial plaster, he tells us, is utterly unfit for use as it will not set within a reasonable time and is heavy and unmanageable. He does not consider a "dinner pad" necessary, but we are not informed why, for variations in the size of the abdomen of no small extent do occur in connexion with food. In severe cases in which the deformity is increasing the author recommends complete rest in bed, and he has seen pale, emaciated little patients, apparently on the verge of the grave, changed in a few weeks into well-nourished, healthy-looking children merely by perfect rest. The best results are to be obtained by keeping the patient completely in bed. Dr. Moore mentions that the form of spinal support which is most frequently sold by instrument-makers is one which depends for its usefulness upon crutches making pressure in the axilla; this form of instrument is worthless, for light pressure under the ever-moving shoulders does not afford support and heavy pressure cannot be borne.

A very good account is given of the treatment of talipes, but we were a little surprised to find the statement that some English surgeons after performing tenotomy still put up the foot in the deformed position and gradually overcome the deformity later. We are not aware of this practice being followed by any English surgeons at the present time. We fully concur in the author's views as to the shape for a tenotome; the ordinary knife has a blade much too long, for its cutting edge is very liable to damage the skin while the tendon is being cut.

Osteoclasis is nowadays very little employed in the treatment of genu varum; Dr. Moore, however, speaks of it as "perfectly safe and very satisfactory." He employs Rizzoli's osteoclast and claims that with ordinary care abrasions of the skin do not occur. He does not recommend it for genu valgum, for he considers it is neither so safe nor so satisfactory as osteotomy owing to the proximity of the joint.

Coxa vara is fairly well described, but it deserves more attention than the three pages devoted to it, for it is probably much commoner than it is usually thought to be. In the treatment of congenital dislocation of the hip the author is inclined to advise first a trial of Lorenze's bloodless method and then should that fail an attempt may be made by a cutting operation to replace the head of the bone in the acetabulum artificially deepened.

The Housing of the Working Classes Act, 1890, and Amending Acts. By CHARLES E. ALLAN, M.A., LL.B., of the Inner Temple and Western Circuit, Barrister-at-Law, assisted as to Practice by FRANCIS J. ALLAN, M.D. Edin., D.P.H. Cantab., Medical Officer of Health to the Strand District Board of Works. London: Butterworth and Co. 1898. Price 7*s.* 6*d.*

ALTHOUGH the Housing of the Working Classes Acts were enormously simplified by their consolidation in the Act of 1890, this latter is in itself sufficiently voluminous and, withal, complicated as to justify the production of a separate volume dealing with its enactments and with the decisions already delivered in regard to them. Mr. Allan has endeavoured to present us with such a work and it must be conceded that his efforts have been for the most part a success, the present volume being convenient both in size and shape and its contents being well arranged. The text of the principal Act and of the four short amending Acts is given, of course, in full, and it is interpolated with clearly expressed explanatory notes. There is, too, a table of cases which cannot fail to be of material assistance to those who have officially to advise local authorities and who have to interpret the exact meaning of certain sections in the light of decisions given in relation to them. The introduction forms a capital summary of the provisions of the several parts of the Act, and this in spite of the fact that the revision of this part of the work has not been altogether perfect; for instance we read on page xxxv. that the ratepayers may appeal to the "Local Government" when obviously the Local Government Board is meant. The appendix contains the several prescribed forms and also the circular of the Local Goverment Board as to provisional orders and as to instructions as to applications for such orders. The index is concise and useful.

LIBRARY TABLE.

Who's Who? 1899. Edited by DOUGLAS SLADEN. London: Adam and Charles Black. Price 3*s.* 6*d.*—*Who's Who?* is improving and this is much to say of any book of reference, although books of this class must improve if they desire to keep their place. There are a great many new features of interest, such as a table of American ladies bearing English titles. Among the addenda are some particulars of the Right Hon. Cecil Rhodes, Mr. F. R. Harris, and Dr. Leyds. There is information of all sorts and kinds and altogether the book will prove exceedingly useful.

A Manual for Students of Massage. By M. A. ELLISON. London: Baillière, Tindall, and Cox. 1898.—Massage properly used is undoubtedly a valuable therapeutic agent. Like electricity, however, it has been so abused by quacks and swindlers that it is still looked upon with a certain amount of suspicion, and any book dealing with the subject not written by a medical man is somewhat discounted. The manual under review, however, seems to us to be a clear account of the various manipulations employed in massage and Miss Ellison has been careful to lay stress upon the fact that no case should be undertaken without medical permission at least, if not medical supervision. This of course is an essential, for the neglect of this canon has perhaps done more than anything else to bring massage into disrepute. The book is illustrated by clear and simple anatomical diagrams indicating the position of the chief muscles. It should prove useful for the class of persons for whom it is intended. Mr. H. H. Hulbert, M.R.C.S., L.R.C.P., supplies a preface in which the medical points of the book are shortly dealt with.

Flash Lights on Nature. By GRANT ALLEN. London: Geo. Newnes, Ltd. 1899. Price 6*s.*—These are a series of papers upon sundry subjects in natural history. Many, if not all, of the essays have already appeared in the *Strand Magazine* but they are quite worthy of being reprinted. We like Mr. Grant Allen far better as a natural historian than as a hilltop novelist, for in these papers we find the observation and fancy which gave us "The Revd. John Creedy" and "Palinghurst Barrow." Insects, plants, birds, and spiders form the groundwork of Mr. Allen's pictures. He tells us all about aphides and their relations to ants and he takes us through the life-history of a spider. Has any one by the way ever considered what an appalling monster a spider would be if it were of the same relative size to a human being as it is to a fly? A creature with eight legs all armed with claws, eight eyes, a mouth provided with two great fangs secreting a deadly venom, and the power of spinning a snare all smeared with a sticky substance. Imagine a wretched man struggling in one of these death-traps. We are glad to see that Mr. Allen has a word of praise for the earwig. It is a not altogether undeservedly maligned creature but withal a most interesting one. Its

Digitized by Google

life history and the method by which its wings are folded up go far to redeem its bad character—which we own with sorrow it deserves—of damaging flowers. Mr. Enock's admirable illustrations help to make his collaborator's text plain at a glance; not that we mean by this that Mr. Grant Allen writes unintelligibly, but "things seen are mightier than things heard." The book will make an admirable gift for any person who cares for country life, and even for the town dweller it will be useful, for he can see many of the subjects dealt with in the parks and open spaces.

Traité Pratique de Radiographie et de Radioscopie: Technique et Applications Médicales. (A Practical Treatise on Radiography, Radioscopy, and their Medical Applications.) Par A. LONDE. Paris: Gauthier-Villars. 1898. Pp. xii. and 244. Price 7 francs.—In this comprehensive work M. Londe, who is at the head of the photographic and radiographic department of the Salpêtrière, gives many fine reproductions of radiographs of bones not only in normal subjects but in malformations and also when presenting lesions due either to injury or disease. In undeveloped persons the progress of ossification may be observed and two interesting examples of this kind are illustrated, one of them being the hand of an Egyptian mummy which from the state of the ossification was inferred to be that of a child eight years of age. The other case was that of a male patient, nineteen years of age and 41 in. high, admitted to the Salpêtrière with myxœdema. Ossification was hardly more advanced than in a child of two or three years, but after five months' thyroid treatment he was 1¾ in. taller and the radiographs taken then showed the bones of the hands and feet to be much better ossified than on the former occasion. In the chapter on foreign bodies embedded or swallowed, in addition to the ordinary method of passing the rays through the part in directions at right angles to each other, M. Londe describes four special contrivances for assisting the observer. One is a device of his own, a boxwood triangle with metallic pins projecting from it, which are photographed at the same time as the foreign body. Two of the other methods require the simultaneous use of two vacuum tubes; they have been suggested by M. Brunel and Dr. Foveau de Courmelles and by Dr. Mergier. Various contrivances for use with fluorescent screens are shown and there is an illustration of Dr. de Bourgade's clinical table on which an infirm patient may be laid; being hinged it can be inclined to a considerable extent and the observer can sit on a low chair underneath it when either using the fluorescent screen or placing photographic plates in position. The chapters on sources of electricity, various kinds of vacuum tubes, screens, &c., are tolerably full and altogether the book is one which can be recommended.

JOURNALS AND REVIEWS.

IN the December number of the *British Journal of Dermatology* the original part is entirely taken up with the report of an interesting debate on general exfoliative dermatitis, introduced by Dr. Walter Smith at the Dermatological Society of London. It is valuable as giving the views upon this serious disease of the skin held by some of the leading British dermatologists. The quarterly survey of dermatological literature and the report of the Dermatological Society of Great Britain and Ireland complete the number.

Archiv für Dermatologie und Syphilis. Band xlvi., Heft 3. (*Archives of Dermatology and Syphilis.* Vol. xlvi., No. 3.)—This number contains an article by E. Doctor on the Relationship of Darier's Disease to Ichthyosis, in which he concludes—(1) that Darier's disease is connected with the hair follicles and sweat gland ducts with hyperkeratosis; (2) that it is generally but not always associated with hyperkeratosis, and that the so-called Darier's bodies are partly evidence of the parakeratosis but do not form a feature peculiar to the disease, as they may occur in other kinds of cell degeneration; and (3) that Darier's disease is a variety of ichthyosis from which clinically it may be distinguished by its localisation and by the presence of Darier's papules and histologically by the proliferation of the papillæ and of the rete Malpighii. J. Schutz writes on the occurrence of leucoplakia oris in psoriasis and other dermatoses and gives the evidence contained in dermatological literature that psoriasis may attack mucous membranes. H. Apolant has a long paper on Antipyrin Eruptions, the literature of which is sufficiently formidable, amounting to four closely-printed pages of references. H. Napp and C. Grouven conclude the original articles with the results of the TR. Tuberculin treatment in the Dermatological Klinik at Bonn. Their experience, like that of others, is that while it exercises a beneficial influence on the tuberculous processes, too often the good effect does not last and the disease returns. At the same time whatever benefit accrues is not accompanied by injury to the rest of the organism. The remainder of the number contains the usual reports of German dermatological societies and abstracts from recent literature.

Scottish Medical and Surgical Journal.—In the December number Dr. Alexander James (Edinburgh) gives clinical details regarding 4 cases of Tuberculous Neuritis, the parts affected being both legs and feet in two cases, the left arm in 1 case, and the right arm, right leg, and right side of the face in the remaining patient. In connexion with this subject Dr. James discusses the so-called "causeless hemiplegia" which may occur in tuberculous persons and he describes an instance which he considers to be of this kind. Dr. T. McHardy (Cullen) gives an account of a patient who had suffered from chronic gastric ulcer for twenty years, but found complete relief from all symptoms after taking $\frac{1}{10}$th or $\frac{1}{12}$th of a grain of bichromate of potassium every six hours for twenty-two days. Dr. W. Stewart McDougall describes a case of Ascites in which paracentesis was performed over 100 times. The patient is a female pauper in Sutherlandshire; in five years over 4000 pints of fluid have been removed from her abdomen.

Dublin Journal of Medical Science.—The original articles in the December number are by Dr. T. W. Grimshaw on the Relations between Preventive Medicine and Vital Statistics; by Dr. R. H. Kennan on "Relapse" in Scarlet Fever; and by Dr. J. W. Moore on Clinical Experiences of Septicæmia and Enteric Fever.

Manchester Royal Infirmary Students' Gazette.—An article in the November number entitled the English Student in Vienna and written by Mr. F. H. Westmacott contains a good deal of miscellaneous information which can hardly fail to be useful to English visitors arriving in the Austrian capital for the first time. It seems that hospital work there begins at 7.0, 7.30, or 8 A.M. and goes on till 7 P.M. The Pathological Institute is "open day and night."

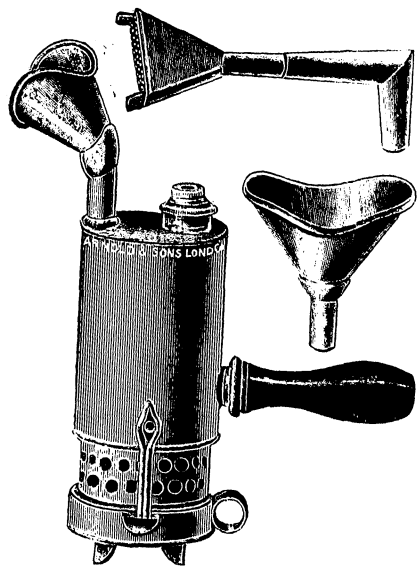
DIARIES.

LETTS'S well-known diaries (Cassell and Co.), in their 1899 editions, are as comprehensive as usual, ably supplying the needs of the office, the home, and the individual, whilst the "Medical Diary" continues to provide members of the profession with a handy note-book, conveniently carried in the pocket, in which may be recorded the names of patients visited each day, lists of nurses with their residences, midwifery, vaccination, and Factory Act engagements, things wanted and lent, and accounts rendered, &c. There is also given much useful information which is sure to be needed at some time.

Wright's Improved Physicians', Surgeons', and Consultants' Visiting List (John Wright and Co., Bristol) is presented in three different forms. Forms A and C are the usual

Digitized by Google

annual editions, and form B, designed for perpetual use, is not restricted to any particular month or year. No doubt this latter feature has its advantages in not a few cases, and particularly so in very small or very extensive practices. The compiler of all three is Mr. Robert Simpson, L.R.C.P., L.R.C.S. Edin. The usual provision is made for recording in a convenient form the details of visits made and of engagements entered into, nurses' addresses, cash accounts, &c. Form C also supplies the needs of practitioners who are certifying surgeons under the Factory and Workshops Act.



Smith's Physicians' and Surgeons' Visiting List, Diary, &c., for 1899 (Hazell, Watson, and Viney, 52, Long-acre, W.C.) is the successor of fifty-two previous issues, and is therefore well advanced in the good opinions of the profession. Provision is made for jotting down the usual visits, engagements, &c., in a form convenient to the busy practitioner, and the varied information at the beginning of the diary adds materially to its value.

From Messrs. Bemrose, 23, Old Bailey, E.C., comes a *Monthly Diary* which provides twelve handy little notebooks, one for each month in the year, suitable for carrying in the waistcoat pocket, and useful for jotting down those many little items which, when once thought of or come across, the busy man finds it absolutely necessary to "make a note of" if they are to be rescued from oblivion.—A similar idea is carried out in *My Month's Engagements, Diary, and Memoranda* (R. Bridges and Co., 92, Chancery-lane, W.C.), the twelve monthly parts being provided with a neat leather case, with pockets, which has the merit of being thin and therefore not cumbersome.

New Inventions.

A NEW FORM OF WARM DRY AIR INHALER.

THE indiscriminate use of steam inhalation in bronchitis and other respiratory affections I hold to be a mistake, and I am quite satisfied that better results can be had (in some cases, at least, of chronic or acute bronchitis) by the use of hot-air inhalation. The illustration represents a form of portable inhaler made at my suggestion by Messrs. Arnold and Sons, Smithfield, which so far as I can discover is the only inhaler of this kind that can be held in the hand of the patient. One mouthpiece acts as a funnel for filling the receptacle with boiling water, a constant temperature being maintained by a spirit-lamp underneath. There is another mouthpiece enclosing a piece of felt or spongiopiline, into which any medicament which may be selected can be dropped and the hot air drawn through, thus medicating the air inhaler.

The inhaler consists of a cylinder containing a spiral tube like the worm of a still; one end forms the core of the handle through which the outer air enters, the other end communicating with the mouthpiece.

Cheltenham. ALEXANDER DUKE, F.R.C.P. Irel.

PUBLIC VACCINATORS IN THE WEST OF ENGLAND.

THE "tremendous experiment" continues to give rise to a crop of arguments and discussions in many parts of the country. The matter came up before the Okehampton Board of guardians on Dec. 10th and it was stated that, taking last year as a basis when the fees paid for vaccination amounted to £31, the minimum offer made by the committee would be £81, but that on the scale demanded by the medical men the sum would be £118. One of the committee said that if every union adopted the terms which the medical men asked in that union the cost to the whole country would be half a million instead of as in last year £89,000. The committee understood that "all the vaccination medical men in the country held a conference and that the fees to be accepted were fixed at that conference." Eventually it was decided that the fees demanded could not be paid. The matter now rests with the Local Government Board.

At Camelford on Dec. 9th Mr. Jerome and Mr. Wade appeared before the board of guardians with regard to fees. The minimum was 5*s.*, but they asked 8*s.* 6*d.* Mr. J. Taylor of Trevalga proposed giving 6*s.* 6*d.* Mr. Venning of St. Cleather proposed to give the minimum and this was carried by 14 votes to 12. The medical officers refused to accept this and the matter was adjourned for a fortnight.

At Bodmin on Dec. 10th a long discussion took place without any definite decision being arrived at.

At Helston, on Dec. 10th, the vaccination committee recommended in connexion with the new Act that a fixed fee be paid in all cases, to include mileage; that the district for vaccinating purposes be rearranged; and that the vaccination officers be paid 3*d.* for every birth registered, 1*s.* for every registration of successful primary vaccination, and 9*d.* for transmitting a certificate to another district. The committee had also considered the replies from the several public vaccinators, all of whom, except Mr. Leverton-Spry of St. Keverne, asked for a registration fee of 2*s.* 6*d.* instead of 1*s.* offered by the board, but otherwise accepted the scale of fees offered. Mr. Leverton-Spry was now willing to accept 1*s.* registration fee. The committee decided to adhere to their original offer of 1*s.* It was proposed that if the medical men did not accept the 1*s.* registration fee to apply to the Local Government Board to elect one medical officer for the whole union. The present holders had been served with twenty-eight days' notice to terminate their present contracts so as to give the board of guardians a free hand. The resolutions were carried. We do not quite understand by what right the Helston Board of Guardians have given their public vaccinators twenty-eight days' notice so as to have a free hand, unless, indeed, there was some clause in the original contract bearing on such a notice. The Vaccination Memorandum of Oct. 18th, 1898, says (Art. I., par. 1.): "Provided that nothing in this article shall affect the validity of any contract for public vaccination made under any Order hereby rescinded."

At Barnstaple the vaccination committee having met the public vaccinators of the union recommended to the Barnstaple Board of Guardians the following scale of fees:—Art. 3 (*a*) 2*s.* 6*d.* instead of 1*s.*, as the committee considered the latter fee too small for the amount of work; and (*b*) 5*s.* for each successful case of vaccination and also a fee of 1*s.* per mile for each visit after the second mile, but in no case is the total fee to exceed 2 guineas except by a special order of the board. The guardians adopted this resolution.

DIPHTHERIA IN CARDIFF.—The medical officer of health of Cardiff (Dr. Walford) in his report to the Health Committee on Dec. 13th stated that for the four weeks ended Dec. 3rd 78 cases of diphtheria had been notified, compared with 32 in the preceding four weeks. Dr. Walford added that the whole of the surrounding districts of Glamorganshire were suffering from an increase in the number of cases of diphtheria.

THE LANCET.

LONDON: SATURDAY, DECEMBER 24, 1898.

RECENT proceedings regarding the Vaccination Acts by magistrates, boards of guardians, and anti-vaccinationists furnish much food for reflection. They indicate, indeed, that the year 1899 may witness a serious struggle between law and order on the one hand and the forces of anarchy on the other. The purpose of the conscience clause was to distinguish between genuine and deep-seated objection to vaccination and parental carelessness and neglect of duty. The clause was to make this distinction by imposing on those who chose to take advantage of it a considerable expenditure of time and trouble. That was the purpose of the clause, but unfortunately it was so drafted that such an interpretation is not at all obvious and in various parts of England magistrates are administering it in such a way as to afford no indication whatever of the reality and seriousness of alleged objection. This fact has become specially prominent with reference to the tens of thousands of children who have within the last fourteen years remained unvaccinated notwithstanding the requirements of the Acts of 1867 and 1871. Under the new Act a period of four months from the date of the coming into operation of the conscience clause was allowed to the parents of all such children either to get them vaccinated or to obtain relief certificates. The four months ended on Dec. 12th and within a week or two previous to that date various communities in which vaccination had been neglected seemed to waken up to the knowledge that the period of grace (if so reputable a word as *grace* can be used in such a connexion) was about to expire. The result was that various benches of magistrates arranged for special and repeated sittings, in some places for several hours night after night, and that at such sittings all attempt to ascertain the existence of conscientious objection was practically abandoned and the whole proceedings were reduced to a mere scramble for entrance into, and exit from, a crowded court-house, with the formality of obtaining in the course of crushing through the court-house a couple of hurried signatures to a printed document which had previously perhaps been purchased for a copper or two at the counter of some neighbouring bookseller. Such proceedings, of course, have not actually increased the amount of non-vaccination in such places. They have, indeed, provided in a rough and incomplete fashion a register of the unvaccinated juvenile population. It is, however, a matter of grave public concern that this line of action should have been followed, for it may have prevented the protection against small-pox of many thousands of children whose careless parents in the absence of so absurdly easy an alternative would have given their offspring the benefit of the Jennerian preventive rather than face prosecution and fine under the new Act. At Oldham, for instance, some time before Dec. 12th, the Mayor, who evidently sympathises with anti-vaccination, wrote to the local papers as follows: "Very few applications have hitherto been made, the reasons, in my opinion, being the inconvenient hour at which the courts sit (10 o'clock in the morning) and the charge which is made for the certificate. Conscientious anti-vaccinators regard this charge as a sort of penalty for their convictions. These two objections ought to be removed." And they were removed with a vengeance by the Mayor who with his colleagues sat night after night and hour after hour granting certificates to objectors whose conscientiousness (or the want of it) he had no possible time to consider. The result is said to be that some 30,000 certificates have been granted in Oldham, and but for the action of the Mayor many of the children so certified might have been submitted to vaccination by their parents. It is also a matter of concern as to whether in future with regard to children approaching the age of four months the same farcical interpretation of the Act will guide magistrates, or whether they will endeavour to carry out the spirit and purpose of the conscience clause by making it something else than a sham.

Certain other things, however, are being said and done with reference to the new Act which may turn out to be of even greater importance than these and which may raise questions going far beyond the scope of anything closely related to vaccination. Various boards of guardians influenced by various prominent anti-vaccinationists seem to have deliberately decided to defy Parliament and the nation with regard to this matter. Evidence of this was furnished at a Congress of the National Anti-Vaccination League recently held at Lincoln. Looking to the magisterial proceedings above referred to and to the fact that such proceedings could not have taken place if the Government had properly drafted its conscience clause so as to say definitely what was to be done under it, we can with difficulty dissent from the opinion expressed by one member of the League that "the conscience clause was a mockery and a sham" and that it makes "a bigger muddle of the Vaccination Acts than ever"; or by another, that the recent Act is "one of the most ridiculous known in the English law." That, however, is not the point of greatest interest in the deliberations of the League. Though as a body they did not venture to pass any resolution advising wholesale refusal of the conscience clause it was freely stated that certificates ought to be applied for only where anti-vaccinationists were in evil case but that where they were strong there should be no such compromise. Councillor BIGGS of Leicester is reported as having said that "the Leicester Board had simply acknowledged the receipt of the Local Government Board's communication and laid it on the table. They had defied the Local Government Board in the past and that would be their attitude in the future." As to the conscience clause anti-vaccinationists "ought to have nothing to do with it whatever." A Halifax representative declared that "he knew this—if a town was against a certain thing and the body representing the town was against it the Local Government Board would let them severely alone." In the Market-place at Leicester a public meeting was recently held at which it

Digitized by Google

was decided neither to submit to vaccination nor to apply for certificates of exemption. It is such proceedings as these that we look on as indicating the possibility, or even the probability, of an early struggle between the civil power and the forces of anarchy. The previous Vaccination Acts, though usually spoken of as compulsory, were not so in any real sense of the term. Even when faithfully administered by local boards all that the Acts did was to offer the two alternatives of payment of penalties and submission to vaccination, and when boards neglected their duty parents were left entirely free to do as they chose in the matter. This experience of license to set aside the law in the past is now bearing its fruits in the expressed determination of men like Mr. BIGGS and of the Leicester Board of Guardians to defy the law in the future. The national Legislature has gone a very long way in its anxiety to make it easy for anti-vaccinationists to obey the law of the country. Though Parliament and the Ministry and the Royal Commission on Vaccination agree with the medical profession in believing that vaccination is essential to the prevention of small-pox they yet, as a matter of expediency, determined to allow parents alleging them selves to be conscientious objectors to neglect the protection of their children against the scourge of small-pox. All that the country, as represented by Parliament, determined to ask was that every parent so objecting should take the time and trouble to make known his objection in a manner provided by the law. We have seen how in various parts of the country magistrates have gone much further than Parliament intended and much further than they ought to have gone in making it easy for parents to procure exemption from the operation of the Acts. Yet in the face of all this we find boards of guardians and responsible individuals deliberately deciding to disobey even the provisions of the new Act and to flout and defy the national will as expressed by Parliament. We find also that throughout the country, under the influence of the League or of its branches or of local agitators, probably thousands of parents of unvaccinated children under fourteen years of age have refrained alike from procuring their vaccination and from obtaining certificates under the conscience clause. The conciliatory offer has been ostentatiously rejected and the Government and Parliament are openly defied. The Local Government Board is told that past experience shows that, so far as it is concerned, it will yield to such defiance. In view of all this we have no hesitation in saying that great as is the importance of the prevention of small-pox epidemics in this country what is now at stake is infinitely greater. The question simply is whether the executive Government will cease to govern, whether Parliament will cease to care for the enforcement of its own enactments, and whether the national will as expressed by law shall be disobeyed with impunity. Never in the history of this country has more been done to make easy the obedience to the law. In the case of many foolish persons the effect has been to inflame their self-conceit, to increase their unreasoning obstinacy, and to confirm them in their opinion that the law can with safety be defied. That is the state of things with which the Government has now to grapple, and we repeat that the year 1899 is likely to see on this subject a constitutional struggle the results of which will have effects reaching far beyond the question of vaccination to which the struggle will have owed its origin.

WHEN the claims of public health come into conflict with those of fine art and history which of the two must be recognised as the stronger? Such is the question raised perennially in modern life when centres of population have to adjust or remodel themselves to the growing wants of the many—a question familiar to us in the British Isles but still more urgent in the lands washed by the Mediterranean, in which a remoter and fuller past is daily feeling the demands of a more exacting, because more imperfectly furnished, present. Our lay contemporaries have been giving prominence to the question chiefly as it affects Italy, whose political resurrection has brought and is bringing with it much disturbance, if not actual effacement, of monuments ancient and mediæval and whose centres of art treasure and historic association, like Florence and Rome, are being shaken to their deepest and innermost recesses by the architectural and sanitary rehabilitation imposed by the "new order." There is no doubt that by the building operations following on the necessary demolitions indicated much that is interesting, even precious, must disappear, but, on the other hand, much undeniable improvement and indispensable convenience is being effected; and so the question stands as we put it at the outset—which of the two exigencies, social and sanitary or artistic, is to have the preference? The old answer "salus populi suprema lex" seems the only possible one, even if it take the uncompromising version given to it by Italy's patriotic surgeon and author of her "Codice Sanitario," AGOSTINO BERTANI, who "per la salute di un solo individuo avrebbe distrutto il distruggibile" (would, for the health of one single individual have destroyed the destructible). But while insisting on the imperative claims of humanity to the normal conditions of life—fresh air, pure water, sound food, and commodious house-room—do we thereby ignore the interests of art with its creations or history with its monuments? Not so. It is possible to meet both demands, as, indeed, it is only by concurrently satisfying their respective claims that either interest can be enjoyed at its best. Art without health is even a worse condition than health without art. The world has never seen such a repertory of *chefs d'œuvres* in architecture, sculpture, and painting as Athens presented just before the Peloponnesian war. But the plague which early in that contest reduced the "City of the Violet Crown" to a lazaretto or charnel-house would have made PERICLES view the triumphs of PHIDIAS and ZEUXIS as so many eyesores could he have known that half the treasure which they cost would have obviated the overcrowding and the neglect of all sanitary law which incurred deadly Nemesis and brought himself, his family, and thousands of the fellow-citizens whom he loved to a premature and loathsome end.

This "lesson of history" was present to the mind of the Marchese TORRIGIANI, Mayor of Florence, when in the Chamber of Deputies the other day he thanked the company of British artists and men of letters

Digitized by Google

for their solicitude about the monuments of his city threatened as they were supposed to be by its necessary expansion and readjustment, but reminded them that humanity also had its claims and that to lead a healthy and normal life is man's first condition, without which art and literature are, at best, but "vain deluding joys." In further indication of his position he appealed to the Minister of Public Instruction, Dr. BACCELLI, himself a jealous conservator of historic and artistic treasure (witness his excavations in the Forum, on the Sacra Via, and on the Palatine), and drew from him an eloquent outburst on the claims of "la vita moderna" as not irreconcilable with those of history and fine art, followed by an expression of the fullest confidence in the Florentine committee appointed to safeguard the traditional attractions of the city. Moreover, as Dr. BACCELLI himself has put in evidence, the demolitions so dreaded by the foreign dilettanti have resulted in the unearthing of treasure-trove far more interesting and far more precious than the structures which they removed, till it has really come to be a question: Is it only mediæval monuments that are to be respected, and are there not records of a yet auguster past to be disclosed from beneath those pre-Renaissance edifices? The excavations of the "Centro" of Florence have resulted in a "true conquest for Etruscan art," and for that of the Roman epoch, as a visit to the Museo della Crocetta will demonstrate, and yet further relics are doubtless in store for the art student and the historian as the result of the demolitions so peremptorily "vetoed in advance." The late Dr. KING CHAMBERS, in his brilliant paper on the Climate of Italy (in great part reprinted from THE LANCET), described mediæval Florence as a series of "Hanway-passages bordered by Newgate prisons." He was no "Philistine"—on the contrary, he was a scholarly and artistically cultured physician; but his vote would certainly have supported the Marchese TORRIGIANI in his preference for light to gloom, for fresh air to foul, for the conditions of health to those of disease, all the more when he had the Marchese's assurance that artistic treasure and historic tradition would be duly respected, or, if subordinated to the *salus populi*, would in process of removal bring to light even yet more precious monuments, to the enrichment of the museums and to the increase of the attractions of the Tuscan "Modern Athens."

SOME amateurs are about to try a bold but very questionable experiment in Birmingham, one deeply affecting the interests of the medical profession and of the public. We say "some," but as far as our information goes at present we should speak only in the singular number. It is an experiment in a branch of medical practice which has hitherto been considered somewhat sacred. Mr. ARTHUR CHAMBERLAIN of Birmingham proposes to establish a consulting department in some central part of the city, to be served by young consultants and specialists who will be guaranteed a minimum salary—"a salary," according to the account of a representative of the *Birmingham Daily Post* who has had an interview with Mr. CHAMBERLAIN, "which would be worthy the acceptance even of the most skilled men among the rising members of the profession." The consulting department is to be for the benefit of, and is expected to be appreciated by, working men, foremen, school teachers, clerks, assistants in shops and persons of the lower middle class. There is to be no hard-and-fast line, we gather, for the exclusion of persons from the benefits of this new departure. "We want a place where a self-respecting, thoughtful, reasonable man or woman who is neither a pauper, an object of charity, nor a millionaire, can obtain the real truth about his or her particular illness and the treatment required for it for a reasonable sum in a reasonable time," &c. There is a wide gap here between the "object of charity" and the millionaire which may include half the patients now resorting to consultants at the minimum traditional fee of one guinea. The fee to be paid under the new *régime* is the modest sum of 10*s*. 6*d* per visit; we presume the fee is to be the same whether the patient comes to the "consulting department" or the consultant goes to the patient.

There is one expression in the above description of what Mr. ARTHUR CHAMBERLAIN wishes to achieve to which we take much exception. He says the object is that the self-respecting man, &c., may obtain the real truth about his illness, &c. Does Mr. CHAMBERLAIN really believe that medical practitioners are divided into two sets, one which gives "the real truth" and another giving a false account of facts? or that among the different grades of the profession there are different methods of detecting and treating and representing disease? We are sure he intends no disrespect to the body of the profession, but we think that he has been unfortunate here in his choice of words and that a little deeper acquaintance with the facts of practice will lead him to know that there is no essential difference in intelligence, in methods, or in candour between the general practitioner and his consulting brother and that they may fairly be trusted to work out the problem of consultation for needful cases between themselves. The fact that a layman should undertake to solve such a problem in a way inconsistent with all the notions of the profession is one to be observed. It suggests that, busy place as Birmingham is, there must still be much unoccupied energy there, but it does not prove anything more. And we cannot say that we are so much enamoured of the results of Birmingham experiments in medical practice and in the support of medical charities that we can afford to hail a brand-new experiment in a branch of practice which has hitherto, as we have said, been free from interference. We are of course glad that Mr. CHAMBERLAIN does not design to create another "great out-patient department where everybody will be seen in an hour and all have to herd together under discipline and pass the doctor at the rate of one a minute," and we note certain but very inadequate precautions against abuse. We cannot forget that in Birmingham very dangerous doctrines of claims to free medical attendance at hospitals have been based on the strength of contributions by workmen—contributions originally designed as charitable doles to institutions for the benefit of those labouring under exceptional ailments or accidents for the treatment of which neither the homes nor the means of working men were adequate.

Most sensible people will ask the question put to Mr.

Digitized by Google

ARTHUR CHAMBERLAIN by his interviewer in the *Birmingham Daily Post*, "Is there any need for such an institution?" and they will answer with a decided negative. If any young and able members of the profession walk into this trap they will do so on their own responsibility and they will lay themselves open to the charge of dealing another heavy blow at the dignity of medical practice in Birmingham. No one acquainted with the facts can maintain that there is any serious difficulty in procuring for the classes named consultation on reasonable terms. As a rule they can well afford to pay the modest guinea fee now regarded as the minimum fee of all self-respecting consultants. For Mr. CHAMBERLAIN must remember that self-respect is not the monopoly of humble patients, but a quality of men who by years of study and most exacting work attain to the grade of consultants and naturally expect their reward. We would urge him to reconsider this proposal and to leave the profession alone to make its own terms with classes whose providence and respectability make them unfit for such experiments as he contemplates. We are glad to see from the account in the *Birmingham Daily Post* that Dr. SAUNDBY and others make forcible objections to this project—a scheme which cannot fail still further to lower the estimate of medical science and the dignity of medical practice.

THE movement to establish a National Association for the Prevention of Consumption and Other Forms of Tuberculosis received a great impetus on Tuesday last, when His Royal Highness the PRINCE of WALES presided at a meeting held at Marlborough House to further the objects of the Association. In so graciously acceding to the desires of the organising committee His Royal Highness has again, as often before, evinced his sympathy with an effort to promote the cause of public health; and it is further significant of his wide interest in this sphere that no sooner was this meeting over than he proceeded to preside at the Council of the Hospital Fund which is linked with his name.

The gathering in support of the National Association for the Prevention of Tuberculosis was a notable one and the promoters of the "new crusade" are to be congratulated upon the inauguration of their work under such auspices as well as upon the moderation with which their aims were unfolded in the "statement" by Sir W. BROADBENT which opened the proceedings. No one can read this statement without being impressed by the need for such an organisation for the enlightenment of the people and the establishment of measures, simple in themselves but founded on scientific facts, calculated to diminish the ravages of tuberculous disease and to promote the recovery of those who are its victims. Indeed, we venture to think that the subject could hardly have been more effectively treated than it was in this statement which may be said to constitute the charter of the Association. For in the first place the extent of the plague which the Association is pledged to combat was clearly set forth in the striking statistics of mortality from tuberculosis in this country; and although it is admitted that from various reasons there has happily been a steady decline in that mortality during the past thirty years, yet the numbers of victims from what is now recognised as a preventable disease are still alarmingly large. Then came the declaration which barely a decade since would perhaps have been received with scepticism in many quarters that tuberculosis is invariably acquired by contagion. It is here that the public will especially need instruction. We should be loth to see in this country the adoption of some of the stringent measures to which Lord SALISBURY alluded as having been in vogue in Italy. The doctrine of the contagiousness of consumption has been held in that country almost since mediæval times and we fear that in consequence much unnecessary harshness has been shown towards, and many hardships inflicted upon, the unfortunate subjects of pulmonary phthisis. But, as Sir WILLIAM BROADBENT plainly averred, mere contact with, or the inhalation of the breath of, the sufferer does not suffice to transmit the contagion. The great risk lies in the lack of cleanliness, in the desiccation of the bacillus-laden sputa, in the absence of ventilation, and, as Sir SAMUEL WILKS wisely insisted, in the exclusion of that powerful bacillicidal agent, sunshine. What is needed is, then, *not* the segregation of the sick or their treatment as lepers, deprived of the care and companionship of those dearest to them, but the intelligent appreciation on the part of the patient and his kindred of the conditions under which the germs of the disease are cultivated and disseminated. Here the question of protection from the transmission of tubercle by the milk and flesh of diseased cattle comes in for debate. The value of the tuberculin test in the early recognition of the disease in cattle, and, as was pointed out by some speakers, the enlightenment of the farming and dairy industries with regard to the necessity of maintaining healthy stock open up fresh fields for the work of the Association. The hygienic principles which lie at the root of the question as regards man may well be kept in mind in the case of cattle, while many will share with Lord SALISBURY the satisfaction which he expressed that nothing in the shape of legislative enactments is to be sought by the Association. The definite pronouncement against the application of the Notification Act to tuberculosis is to be commended, for it was clearly shown that the preventive methods are of such a character as not to require the adoption of a measure which though of proved utility in the more acutely specific fevers might be fraught with many difficulties in such a disease as tuberculosis. The Association has as its main object the enlightenment of the public, and the agencies at its disposal for the dissemination of the comparatively simple and concise rules of conduct and cleanliness are many.

Lastly the novel but highly rational measure of treatment by means of open-air sanatoria will be encouraged by the Association; and in this connexion we may especially commend the munificent offer of the London partners of Messrs. WERNHER, BEIT, and Co. to set aside £20,000 to establish such a sanatorium in this country for a class of invalids who are unable to take advantage of the benefits of foreign sojourn which are only open to the rich. There is no doubt that this example will be followed and that we may expect as the benefit of the open-air treatment becomes appreciated the erection of such sanatoria

Digitized by Google

will be indispensable in lieu of hospitals and infirmaries where so many subjects of pulmonary phthisis are now retained. The experiences in Scotland related by Sir THOMAS GRAINGER STEWART and in Ireland by Dr. J. W. MOORE afford satisfactory proof of the practicability of treatment in such sanatoria even under this variable climate of ours. Many aspects of this question were touched upon at the Marlborough House meeting and it may not be out of place to recall that at the Epidemiological Society last week a paper was read by Dr. A. RANSOME upon this very subject in which he was sanguine enough to predict that in another thirty years but little would be left for us to do against tuberculosis as the disease would be then banished from the land just as leprosy has been. We would fain share this optimism, but we fear that such a consummation will not be attained in so brief a space. Nevertheless, we do believe that the task taken in hand by the newly-formed association which has received so gratifying a recognition from the highest quarters is one which, rightly conducted, may go a long way to secure this desirable end. The arousing of public interest in the question may further contribute to strengthen the hands of the sanitary reformer by insisting upon a diminution of the evils of overcrowding and over-building, the twin curses of modern civilisation.

Annotations.

"Ne quid nimis."

THE ALIEN CRIMINAL.

THE trial which ended last week by the conviction of a man named Schneider for murder once more presses on public attention the fact that London is inundated with foreigners of the poorest kind. This class swells our pauper population. A point, however, which has not been generally heeded is the amount of crime and the number of other offences attributable to people of alien blood. Whether we look at the names which appear at the county courts, the police courts, or the Old Bailey, it is impossible to avoid the conclusion that a disproportionate number of litigants and prisoners are aliens. This is not surprising when it is remembered how much of the scum of foreign countries is emptied on our willing land. From a medico-legal point of view the trial was interesting inasmuch as the plea of insanity was raised by counsel for the defence. The facts were admitted, therefore no other defence was available. The question of insanity in its relation to crime is perhaps the most difficult of all the subjects treated in our courts by medical men and lawyers. That Schneider was condemned to death was probably just. He was not judged by the jury to be of unsound mind when he committed the deed. At the same time, looking at the evidence, can it be said that it was proved that the accused was in full possession of the power of controlling his will at the time? The symptoms of insanity are so deeply hidden that it is often only by accident that they are seen. Therefore in questions of such difficulty it would be as well that the legal maxim should not be driven home too hard that a criminal is presumed to be sane until the contrary is proved—for that is the effect of it. The familiar legal test of insanity is whether the mind of the accused person is so diseased that he cannot know the nature and quality of the act he is committing or, if he knows it, that he does not recognise its wrongfulness. Probably if this test were applied to the acts of lunatics in our asylums the great majority of them would be liable at some time or other to punishment. Yet it is unlikely any one of them would ever suffer the death penalty for murder. As suggested above, a more satisfactory test would be the condition of the criminal's will-power, the power of self-control; and to settle so knotty a point either the judge should have assessors consisting of medical experts and specialists or the jury should consist of these to assist in arriving at a verdict. In the Admiralty Court the judge is assisted by assessors. Surely insanity is as important and difficult a subject as navigation.

MEDICAL AID AND THE LAW.

WE recorded in a note last week that the Court for the Consideration of Crown Cases Reserved had affirmed the conviction of a man named Senior, one of the Peculiar People, who was tried at the Old Bailey before Mr. Justice Wills in November for the manslaughter of one of his children. Seven out of twelve of them have died at different times without medical aid being obtained for them, and the sentence of four months' imprisonment which has now been passed by Mr. Justice Wills seems but a light one. It may, however, act in some measure as a deterrent to those who otherwise might join the sect and it may be increased in future cases. As has, we believe, been pointed out, the perfectly genuine religious beliefs which led to suttee in India or to human sacrifices in other countries now under our rule have not prevented our forbidding such customs and imposing heavy penalties on their observance. The case of Senior is interesting as illustrating the danger of brevity leading to obscurity when statutes are drawn. It is admitted to be doubtful whether there is at common law such an obligation upon a parent to call in medical aid for his child as will render him liable to be convicted of manslaughter should he neglect to do so and should the child die in consequence. An Act, however, was passed in 1868, dealing chiefly with poor relief, which incidentally made it an offence punishable on summary conviction "when any parent shall wilfully neglect to provide adequate food, clothing, *medical aid*, or lodging for his child, being in his custody, under the age of fourteen years, whereby the health of such child shall have been or shall be likely to be seriously injured." It was held in the case of one of the Peculiar People named Downes in 1875 that this Act imposed an absolute duty on parents, whatever their conscientious scruples might be, and that death having resulted from an intentional disobedience of the law the verdict of "Manslaughter" was right. In 1889, however, the Prevention of Cruelty to Children Act repealed the section of the Poor-law Amendment Act of 1868 above referred to and as a substitute made it an indictable offence for a person having the custody of a child to "wilfully assault, ill-treat, *neglect*, abandon, or expose" such child in a manner likely to cause unnecessary suffering or injury to the health of such child. The same expression to "wilfully neglect" is used in the Cruelty to Children Act of 1894 which has superseded that of 1889 and it was on the question suggested by the deliberate omission of all direct reference to medical aid that Mr. Justice Wills reserved the case of Senior for the consideration of his learned brethren. They held unanimously that neglect meant "the absence of such reasonable care as an ordinary parent would reasonably use for the care and protection of his child," in which, of course, the supplying of medical aid was included. That they should so hold and should confirm the conviction of Senior seems only natural; it must not, however, be thought that Mr. Justice Wills reserved the question unnecessarily. It seems that more or less

Digitized by Google

recently Mr. Justice Hawkins directed the jury to acquit one of the Peculiar People on the grounds indicated above. Apparently the consideration did not weigh with his lordship as it did with Lord Russell of Killowen, that it was unlikely that the Legislature intended to take a retrograde step in a matter of humanity. In addition to the light thrown on the evolution of laws by the case which we have commented upon it will be seen how different is the position of a child from that of a grown person where the summoning of medical aid by others is concerned—a difference marked recently by the withdrawal of the charge against the Christian Scientists in connexion with the death of Mr. Harold Frederic.

BICYCLING.

THERE can be hardly a doubt, we think, among those who have considered the subject at all, that bicycling, whether as an exercise or merely as an easy means of transit from one place to another, is likely to increase rather than to diminish among us. Its convenience is too obvious to admit of its falling into disuse, at least among a considerable class of the community. As an amusement no doubt it must, like other amusements, be more or less at the mercy of fashion and increase or diminish in popularity according to the whim of the moment. But as a mode of getting away from towns into the surrounding country, or of going from one part of the country to another, with all the excellent results to the health of the community which that implies, it is evidently destined to remain among us. Since this is so it is perhaps worth while to consider seriously a point with regard to this particular exercise which might be dismissed as relatively unimportant in the case of a mere pastime soon to be superseded by some new invention. Now that bicycling is becoming almost universal among the younger generation of both sexes in the middle and upper classes it is eminently desirable that everything that science can do should be done to make it a wholesome and rational recreation. Some steps have already been taken in this direction. Medical men have pointed out the dangers which lurk in this even more than in other physical exercises when indulged in to excess. They have indicated, both in individual cases and more generally, the ill-effects which even moderate cycle riding may have in the case of persons suffering, for example, from certain affections of the heart. And in addition to this we may confidently believe that individual practitioners have given the matter a certain amount of attention and in the case of individual patients or their children have spoken words of warning where warning was needed. For it is quite certain that while with some persons bicycling as an exercise has proved exceedingly beneficial to the general state of health there are other cases in which through some constitutional weakness either acquired or inherited it is not merely undesirable but even dangerous. Something, then, has already been accomplished by the medical profession in this matter, but something, we think, remains to be done. It is only necessary to watch the troops of riders who are to be met with on country roads or even in London itself to see that through carelessness or ignorance what may be both a graceful and a beneficial exercise is often turned into a harmful and pernicious one. There may be seen men and women mounted on machines which are so ill-adjusted to their requirements that they are quite unable to get the physical benefit from riding which should come from it. The handles are too low, the saddles are set too far back or too low or too high, and the result is that the riders have to adopt an ungainly and from the hygienic point of view undesirable attitude from which they may quite possibly feel serious consequences in the future. It is no uncommon thing, for instance, to see young girls mounted upon machines the saddles of which are placed far too high for them. Their parents naturally in many cases know little or nothing about bicycling. They know still less of the possible ill-effects which riding in a strained or unnatural position may produce, and the question arises how far their medical advisers are capable of helping them. A medical man will of course have no difficulty in pointing out that a bicycle which puts an undue strain upon certain muscles of a child or girl may produce serious consequences. But can he, if he is not an expert in cycling or has not especially studied cycle construction, point out what is wrong with any particular machine and how it should be adjusted to give the maximum of benefit to its rider with the minimum risk of physical injury? In most cases we imagine he could not, and it is not altogether reasonable to expect him to do so. What, then, are the parents or the riders themselves to do? They cannot in most cases trust the agents or dealers from whom they buy their machines. These men very often do not even know the possible dangers which lurk in a machine which does not fit its rider. Moreover, their business is to sell their machines, preferably the machines that chance to be in stock, and they can hardly be expected to point out to a purchaser that they have nothing on the premises that exactly fits him. To do so in nine cases out of ten would merely be to send the purchaser elsewhere for his machine. We confess we do not see any very clear road out of this difficulty. The only hope is that with the spread of bicycling, knowledge of the proper adjustment of a machine and the proper position of handles, saddle, pedals, and the rest relative to the rider and to each other will be so widely diffused that most riders will be able to see after these matters for themselves. There will then be not only fewer cases of actual injury from riding, but the positive good effects of a useful and pleasant form of exercise will be enhanced.

THE DANGERS OF ANÆSTHETICS IN CASES OF INTESTINAL OBSTRUCTION.

A FATALITY under an anæsthetic which occurred at the Sussex County Hospital illustrates the extreme difficulty and danger of giving anæsthetics to patients in whom, owing to intestinal obstruction, the contents of the bowels regurgitate into the stomach. The patient in this case was a man, aged thirty-eight years, whose abdomen was greatly distended as a result of three days' complete stoppage. The lungs were compressed and at the time of admission to the hospital his condition was described as moribund. Frequent vomiting had occurred during the day. The A.C.E. mixture was given from lint by the house surgeon and the head was kept lateralised. As soon as the patient was completely under the anæsthetic "brown fluid" came in a continuous stream from the mouth unaccompanied by retching. The operation proceeded as far as opening the peritoneum when the pulse and respiration failed almost simultaneously. 3 minims of liquor strychninæ and two hypodermic injections of brandy had been given before the anæsthetic. It is not stated whether any of the stercoraceous material had entered the lungs, but in the face of no mention being made of it it is presumable that such was not the case. As has been already pointed out in our columns death in these cases frequently results from the disease itself and the anæsthetic practically is an anodyne to the death struggle. It is the contraction of the diaphragm accompanying the general muscular contraction associated with dissolution which compresses the intestines, causing their contents to enter the stomach. The cardiac orifice, no longer in a condition of tonus, allows the steady flow of the gastric contents along the œsophagus into the buccal cavity. During the death struggle there is often a gasping inspiration which

Digitized by Google

is liable to aspirate the gastric contents from the mouth into the air-passages. In many cases of supposed suffocation by stercoraceous vomitus the entrance of the material into the trachea is not the cause but the consequence of the death struggle. On the other hand, in patients whose condition is less grave there is undoubtedly great danger of aspirating vomitus into the lungs and such a danger is increased in semi-anæsthesia. When the patient's condition allows of lavage by continuous syphon action that proceeding should be adopted; when the asthenia is too pronounced for it the choice of procedure lies between local anæsthesia for the incision in the skin with rapid puncture of the distended gut and general anæsthesia. The great risk of local anæsthesia in these cases is lest fear or shock should give the *coup de grâce*. Probably those who advise this or even the giving of no anæsthetic at all, whether general or local, forget the frequency of death under operation in the pre-anæsthetic period—deaths due solely to "shock." Valuable as are the methods of Schleich and Reclus there is no doubt that they have their limits and the spectre of sudden death haunts such procedures just as it claims a percentage, although happily but a small percentage, of victims when general anæsthetics are employed.

THE GENERAL MEDICAL COUNCIL AND UNQUALIFIED PRACTITIONERS.

ON Dec. 15th at Houghton-le-Spring Joseph Steel was charged with practising as a qualified medical man. Mr. Meynell prosecuted on behalf of the General Medical Council. Mr. Clark who defended said that the prosecution had failed to show that defendant had more than declared himself to be a botanist. In examination the defendant admitted that he had a medical club of 400 members paying from 6*d*. to 9*d*. a fortnight. Defendant was discharged. Mr. Joseph Steel will now be looked upon as a martyr and we make no doubt that his "practice" will increase. He probably knows perfectly well that his patients do not care two straws whether he is or is not qualified. To the ordinary miner a medical man is not one who has passed certain examinations and been put upon a roll known as the "Register": he is simply one who gives sick people a "bottle" when they ask for it. Probably it is dawning upon the north-countryman that there are two classes of medical men—namely, those who can sign certificates under the Workmen's Compensation Acts and those who cannot, but of any other difference the industrial population is to a large extent unaware.

THE "MEDIATE TREATMENT" OF A SYPHILITIC FŒTUS.

AN important lecture on this subject, delivered at the St. Louis Hospital by Professor Fournier, is published in the *Semaine Médicale* of Nov. 30th. Supposing the mother to be healthy but the father infected, is it possible to protect the fœtus? M. Fournier finds that it is—by the administration of mercury to the mother—which he calls the "mediate treatment" of the fœtus. This treatment produces no ill-effects on the mother. If during the first pregnancy of a healthy mother specific treatment is begun early a healthy child will usually be born at term. But the value of the treatment is better proved by cases where a number of abortions have occurred or where several syphilitic infants have been born. When this treatment is adopted a healthy child is born. For example, a young man contracted syphilis in 1881 and was treated for five months. He married in 1883. The first child died on the ninth day from "congenital feebleness." The second child was covered with syphilides and after the fifth week passed into a condition of marasmus and died. The mother underwent a course of specific treatment during the third pregnancy and was delivered at term of a healthy child which at the age of four years was still immune. M. Fournier said that many such cases could be cited. Moreover, under this treatment many complications of previous pregnancies—hydramnios, placental lesions, fœtal dystrophies, hydrocephalus—have been avoided. Treatment of the mother should be commenced as early as possible in the pregnancy and continued through the whole period. Mercury is the important agent but iodine may be advantageously combined with it. After trying a number of preparations M. Fournier has come to the conclusion that the protiodide of mercury in pills is the best. He recommends small doses. "As it is not an adult but a fœtus who is being treated a fœtal dose should be sufficient." But surely this is not convincing. The dose received by the fœtus is not the same as that administered to the mother. However, M. Fournier's observations that successful results may be obtained with daily doses of ¼ gr. and even ⅛ gr. of the protiodide of mercury will receive due weight. There is an obvious source of fallacy—the curative effects of time alone. He adds that it is useless to give large doses to the mothers in cases where they are syphilitic. He recommends an intermittent treatment—twenty days of administration of the drug a month and ten days suspension "to allow the stomach to rest." But others, for example Professor Pinard, recommend continuous treatment.

FOREIGN BODIES IN THE NOSE.

THERE is perhaps no commonplace of medical practice which gives rise to more perplexity and misunderstanding than the diagnosis and treatment of foreign bodies in the noses of children. A short article on this subject in the *Journal de Clinique et de Thérapeutique Infantiles* of Dec. 1st by M. Felizet is therefore of some practical interest, His observations are founded on an experience of 31 cases. The bodies dislodged were of great variety, including dried peas and beans, cherry-stones, slate-pencil, pellets of paper and wool, &c. In all the cases the removal was effected by means of douching the free nasal meatus, either by the hydrostatic method or with a syringe, the injected fluid (tepid water) returning by the opposite nostril and driving the foreign body before it. The pressure of fluid employed in this proceeding is regulated by the resistance encountered or expected, but in all cases it is, at the outset, gentle and applied slowly in order to avoid interference with the action of the velum palati or sudden injection into the Eustachian tube and tympanum. In 26 of the cases noted this method alone sufficed; in 5 the impediment had to be further helped out of the nostril with a forceps or curette. This use of the douche is by no means new. It is noteworthy, nevertheless, both as an aid in the diagnosis and as by far the gentlest mode of treatment in this class of cases. The facts which we have quoted should go far to prove its general efficiency and to obviate at all events in the first instance those more direct instrumental measures commonly advised in surgical text-books.

THE PAY OF SURGEONS TO MINES AND MINING WORKS.

IN our issue of Nov. 12th we commented upon the pay and position of the surgeons attached to collieries throughout the Durham coalfield. The medical practitioners of the Eastern Valleys, Pontypool, Monmouthshire, have now issued a circular in which they point out that the basis on which amounts of payment to medical men are calculated has remained the same for the last twenty-five years, while the working expenses of a practice have practically doubled within the last few years. The necessity of bacteriological research, the increased cost of drugs, and especially of the materials requisite for antiseptic dressings and the like, have

Digitized by Google

all combined to bring about a rise in expenses, while the recent action of the General Medical Council in absolutely forbidding the employment of unqualified men has practically doubled the salaries of assistants. An assistant is of course a necessity, for no man however willing and able can possibly undertake the medical charge of a colliery or large works of any kind single-handed. The memorialists point out that the medical practitioners of the Western Valleys have been for some time paid upon a much higher basis than their medical brethren of the Eastern Valleys and the latter feel sure that such an inequality has only to be pointed out to be instantly remedied. They add that they are quite ready to discuss the matter with their employers, and not only ready but desirous of so doing. We are sure that if such a conference is held the workers of the Eastern Valleys will accede to the prayers of their medical men. This is no question of a club where prosperous tradesmen and town councillors fatten on the charity—for medical attendance at 3*s.* 6*d.* a year is charity—of men who work a great deal harder than they do themselves; it is a question of one set of toilers acting fairly by another set. Within the last twenty-five years or so the position of the average working man has improved wonderfully. Wages have risen, tea is cheaper, tobacco is cheaper, his children get their schooling at other people's expense, while free libraries, washhouses, and baths are found in most places. The collier and the ironworker are sensible men and will, we are sure, see the force of the arguments adduced by their medical men.

CEREBRO-SPINAL FEVER.

WE have received the abstract of a report on the recent appearance of cerebro-spinal fever (epidemic cerebro-spinal meningitis of Stillé) in Chicago in this year (1898) by Dr. W. J. Class. Notes are given of 38 cases, all uncertain and doubtful cases having been eliminated. A summary of the symptomatology of the cases is there given which will well repay perusal. Special attention is drawn to one symptom which the writer believes has not been dwelt upon to any extent in previous reports—namely, difficulty in swallowing. It was noticed in 6 cases, each of which ended fatally. It must therefore be considered as a grave omen in prognosis. As a rule it was found late in the disease when the patient had become semi-comatose, but in one instance it occurred several weeks before death while the patient was still perfectly conscious. Its causation is not clear but Dr. Class deems the opinion plausible that it is due to an accumulation of fluid in the fourth ventricle exerting pressure on the nerve centres in its immediate vicinity which control deglutition. From a consideration of our present knowledge of epidemic meningitis Dr. Class arrives at the following conclusions: (1) that epidemic cerebro-spinal meningitis is to be classed among the contagious diseases belonging to the same category as phthisis pulmonalis; (2) that insanitary conditions exert great influence in affording a proper nidus for the growth of the germs of this disease; (3) that health authorities should receive notice of the occurrence of a case of this disease in order that sanitary defects may be remedied; and (4) persons afflicted with this disease should whenever possible be isolated and all evacuations should be rendered innocuous by the use of antiseptics.

A DEATH FROM ANTHRAX AT BRADFORD.

AN inquest concluded on Dec. 14th at Bradford brought out very clearly the fact that though the Government may make regulations for dangerous trades it is by no means certain that they will be obeyed either by employers or by workmen. The inquest was held upon the body of a wool-sorter named Whalley employed by Messrs. Ickringill and Company. He had been employed in sorting Persian wool and, according to the medical evidence, died from anthrax poisoning, the point of infection being apparently a scratch on the arm. He had slept in the flannel shirt which he wore when at work. The most interesting part of the inquiry was, however, the evidence of the foreman. This official admitted that he knew of the existence of the "Special Rules" as to wool-sorting, No. 2 of which set forth that "all alpaca, Pelitan, Cashmere, Persian, and camel-hair shall be opened over a fan with a downward draught." His answer was: "Yes, I have seen that, but it was not done in this case." In answer to the deputy coroner witness made the remarkable admission that they did not insist on the regulations being carried out—"it was left at the option of the men." He was only a servant and had to follow the instructions of his master. He knew that all Persian wool was to be disinfected as far as possible before opening but that was not done in this case and no disinfectants were used until the deceased went off work. The jury returned a verdict of "Death from anthrax," adding a rider that they were of opinion that such anthrax was caused by non-observance of the regulations prescribed by law for the prevention of wool-sorters' disease. Mr. Wilson, solicitor for Messrs. Ickringill, asked, "By whom?" but the deputy coroner replied, "We don't say." We do not suppose the matter will be allowed to rest here, but in our opinion if employers wilfully neglect to enforce the rules laid down by the Government they should be severely punished, and workmen if they refuse to obey regulations should be at once dismissed.

THE AUSTRIAN PLAGUE COMMISSION.

IN January, 1897, the Austrian Government despatched a Medical Commission to Bombay to investigate and report upon the bubonic plague. That Commission succeeded in collecting a considerable amount of valuable scientific material by establishing itself in one of the most important epidemic hospitals of Bombay, so that before the arrival of the German and Russian Commissions it had already made marked progress in the study of the disease. On Nov. 24th, 1898, the Imperial Academy of Sciences in Vienna issued an exhaustive quarto volume composed of two parts, the first giving a broad general account of the scope and work of the Commission by Dr. Albrecht and the second, or purely scientific division, having a pathetic interest in the mournful fact that its gifted author, Dr. Hermann Müller, fell a victim to the dire disease in Vienna. The Commission commenced its labours on Feb. 24th, 1897, working assiduously until the decline of the epidemic in April deprived its members of "cases" for further study. From a general survey of the report of the Commission we infer that its chief aim was to study the disease from the standpoints of (*a*) etiology, (*b*) pathology, and (*c*) in its purely clinical aspect, the bacteriological and pathological investigations being chiefly conducted by Dr. Rudolf Pöch, Dr. Anton Ghow, and Dr. Heinrich Albrecht. Dr. Müller's clinical observations on the pulse, respiration, and temperature are of the highest practical value. The Commission no doubt encountered serious difficulties dependent largely on the unique system of religious caste in India, on the ignorant suspicion of the friends and relatives of sufferers, and in no small degree on the lack of that proper support which such a noble effort deserved. We are, however, pleased to note that the assistance of medical officers of health and local municipal authorities was willingly extended to the Commission, while the services of an English trained nurse conversant with the vernacular were highly appreciated in many clinical investigations. Dr. Müller very wisely confined his attention to carefully following the development and course of a few

Digitized by Google

individual cases as closely as he could under the circumstances in preference to a superficial examination and hasty judgment on all that passed before his eyes. There is a specially interesting chapter on the Diagnosis of Plague Pneumonia in the Initial Stage. Barisch, the attendant who had charge of the animals in the pathological laboratory of the Vienna Institute, contracted the disease and was at first thought to be suffering from "influenza," a fact which was soon clearly disproved by bacteriological examination, Dr. Müller remarking at the time "that it was a very difficult point to differentiate between an existent pneumonia and the characteristic plague pneumonia." Dr. Müller's conclusions led him to believe (*a*) that the development of the bubo was one of the earliest symptoms of the disease, preceding the profound disturbance of the nervous system; (*b*) that the disease originates in an "infection" through the skin remaining localised for a time; and (*c*) that the systemic or general infection develops from a local centre or focus of origin. He is of opinion that the disease can be divided into main varieties, one affecting the lymphatic glands and the other the lungs. We are struck by the thoroughness of the Commission's work as shown by the fact that clinical and anatomical investigations were always conducted *pari passu*. Separate sections of the report treat of the effects of the bacillus on the nervous system, on the organs of digestion, on the kidneys and bladder, and on the blood, while others touch upon the influence of age, race, sex, and occupation, the period of incubation, the manner of infection, of prophylaxis, and of the whole question of natural immunity. One important conclusion is drawn by Dr. Müller—that is, that because the infection has remained localised or has become constitutional it is impossible to accurately determine the future course and prognosis of the disease, a bacteriological examination being alone a decisive test. The volume closes with an appendix on the fatal illness of Dr. Müller written by his colleague Dr. Rudolf Pöck. In a future issue we hope to give a more extended notice of this report.

FIRES IN LUNATIC ASYLUMS.

FIRE in the wrong place is always more or less of a tragedy, but in a lunatic asylum the occurrence of a fire has special features which excite the concern of the public. An inquest was recently held on the body of Mr. William Cade, aged sixty years, who was suffocated on Dec. 15th at a private asylum, Beckenham-lane, Catford, the property of Dr. Charles Arthur Mercier, a gentleman of large experience and much authority in all questions of insanity and touching the organisation of asylums. After being assistant medical officer in various asylums Dr. Mercier became proprietor of the present establishment twelve years ago. The patient whose death was the subject of the inquest was aroused at the time of the occurrence of the fire, at 3 A.M., but it was considered that he was capable thereafter of attending to himself. At 3.51 A.M. station-officer S. Norris (called at 3.42 A.M.) in charge of the Catford fire station at Rushey-green (1½ miles and 100 yards from the asylum), arrived with engine and escape—the escape run by hand. The fire was extinguished in from 15 to 20 minutes. On the arrival of Mr. David Wall, the officer in charge of the fire station at Greenwich, just after 4 P.M., the patient was found to be missing and was searched for. With a handkerchief over his nose and mouth Mr. Wall crawled into several rooms and finally discovered Mr. Cade on the floor. Although overcome by the smoke Mr. Wall brought him out, but in spite of Dr. Mercier's efforts life was found to be extinct. On the alarm being given Dr. Mercier rang up the Telephone Exchange, but got an answer after some delay that they could not call the fire brigade but would continue to try. The telephone inspector at the Bromley Exchange essayed to call up the Volunteer Bromley Fire Brigade but could get no answer. Superintendent Dowell said that if the Bromley Exchange inspector had rung up the London Exchange they would have communicated with the headquarter staff at Southwark who would instantly have ordered on the Catford and Greenwich engines by telephone. The jury adopted this view and expressed it in the following rider: "That much valuable time might have been saved if the operator of the National Telephone Company at Bromley had been instructed to communicate direct to the London Fire Brigade." The obvious lesson of the event is to perfect the coördination of the telephone companies and the different local fire brigades and to make much clearer and simpler the instructions for getting immediate communication. There should also be on the premises of every asylum a means of dealing at once with fire and the officials should be drilled in the use of all appliances and means of rescue.

THE CASE OF BLACKMAIL.

MR. JUSTICE HAWKINS on Tuesday last sentenced the two elder brothers Chrimes, Richard and Edward, to twelve years' penal servitude and the younger brother, Leonard, to seven years' penal servitude for blackmail—the punishments being righteous retribution for vilely cruel and cowardly offences. The circumstances of the case form a terrible illustration of the evils which are done by such advertisements as we are now dealing with in a series of articles entitled "Quacks and Abortion: A Critical and Analytical Inquiry," and we note with pleasure that the jury in finding the prisoners guilty added the following rider to their verdict:—

"The jury feel that such a vile plot, even with all the ingenuity displayed in it, could only have been possible by the acceptance of such immoral advertisements by a section of the Press—religious and secular—well knowing their nature. The jury further express their earnest conviction that means should be found to suppress such advertisements and the institutions from which they emanate, as they consider them direct incentives to ignorant and evil-minded women to commit crime."

THE EDUCATION DEPARTMENT AND BILLROTH'S "CARE OF THE SICK."

WE have received from Mr. J. Bentall Endean, of Casatrio, Cockington, Devon, printed copies of letters which have passed between him and the Education Department, Whitehall, the correspondence extending from last June to November. Mr. Endean is the author of the English translation of Dr. Th. Billroth's "Care of the Sick at Home and in the Hospital." From a review of this book in the *School Board Chronicle* of May 21st he learned that "Ambulance" and "Sick Nursing" had become "special subjects" in the New Code for evening schools and, to quote his own words, he found "on comparing the syllabi of these subjects on pp. 12 and 13 of the New Code with 'The Care of the Sick' that these syllabi are based upon and are mainly drawn from J. Bentall Endean's English edition of 'The Care of the Sick,' for it is impossible to place the said syllabi side by side with the book without realising that the former are abstracted and constituted almost wholly from the latter." Mr. Endean thereupon asked Sir John Gorst, Vice-President of the Committee of Council on Education, "if compatible with the arrangements of your Department, if it would not be well that the teachers throughout the kingdom should be made aware that the principal text-book on these two 'special subjects' is 'The Care of the Sick,' by Dr. Th. Billroth"? The letters from the Education Department did not dispute the coincidences between the wording of the syllabus and that of Mr. Endean's translation, but stated that "it is the established practice of this Department not to recommend

Digitized by Google

the use of any particular books in public elementary schools." Mr. Endean complains bitterly that the course taken by the Education Department is in fact plagiarism and infringement of his copyright without acknowledgment, and his grievance appears to be a real one but it is difficult to suggest how it can be remedied.

JENNER INSTITUTE OF PREVENTIVE MEDICINE.

THE Jenner Memorial Committee having decided some time ago to transfer any funds which it might obtain to the British Institute of Preventive Medicine the council decided to alter the name "British Institute" to that of "Jenner Institute of Preventive Medicine" and in this way to commemorate permanently the memory of Jenner and his work. The legal formalities have now been completed and the institute will in future continue its work as the "Jenner Institute of Preventive Medicine." The syllabus for 1899 which has just been issued gives a full account of the departments which have been organised at Chelsea.

AN ACTION FOR MALPRAXIS.

A CASE was recently tried by Mr. Justice Darling in the Nisi Prius Court in which John Cole Baxter, aged sixteen years, through his father sued Dr. Adam Macvie, a medical practitioner of Baildon, for £500 as damage for alleged negligence. In the summer of 1896 the plaintiff's father took a house at Baildon Moor and on August 14th of that year the plaintiff while attempting to jump a stream fell and cut his knee on a broken glass bottle. Dr. Macvie was sent for and according to the plaintiff's case was shown some broken glass which had been found adhering to the boy's clothes. The defendant looked at the wound and without washing or probing it stitched it up On the third day there was a good deal of swelling and the defendant ordered poultices. Suppuration apparently occurred and the defendant removed two pieces of glass. On Aug. 26th Dr. T. C. Denby of Bradford examined the wound and the boy was removed to the Bradford Infirmary, where sundry incisions were made to let out matter. The boy remained in the infirmary until Nov. 25th. He had since suffered from a stiff joint. Various medical witnesses, such as Mr. Herbert White of Bradford, Mr. W. Whitehead of the Manchester Royal Infirmary, and others, gave evidence that in their opinion the wound was properly and prudently treated on the whole, although Mr. Whitehead said that he should not have put in stitches without a thorough examination and cleansing. Eventually the jury returned a verdict for the defendant. We congratulate Dr. Macvie upon the result of the action, but to our minds the most interesting feature in this case is the fact that a boy whose parents are presumably in a good position—the father is described as being a partner in the firm of Jabez Cole and Co., Bradford, and he apparently could afford to take a house for the summer—is allowed to lie for three months in a charitable institution. This fact, we consider, wants an explanation.

GENERALISED PNEUMOCOCCIC INFECTION IN PNEUMONIA.

AT the meeting of the Société des Hôpitaux of Paris held on Nov. 25th M. Duplocq and M. Lejonne related a case of pneumonia remarkable for the multiplicity of the complications. The patient was a robust man, aged fifty-nine years. The course was peculiar; there were consolidation in the left axillary region and generalised bronchitis in the right lung. On the ninth day a second focus of consolidation appeared at the left base and he expectorated for the first time two thick, viscid, greyish masses containing numerous pneumococci. On the thirteenth day a third focus manifested itself by fine crepitations at the right base and there was a well-marked swelling occupying the left subclavicular region and shoulder. Next day the œdema had disappeared but there were two communicating abscesses in the neighbourhood of the shoulder; the pus contained pneumococci. Arthrotomy was performed, a tumblerful of pus was evacuated, and the joint was drained. On the sixteenth day a fourth focus of consolidation showed itself by fine crepitations and there was tubular breathing in the left supra-scapular and subscapular regions. The patient improved and the discharge of pus from the shoulder diminished. But on the twentieth day a fifth focus appeared in the right supraspinous region, and on the twenty-second a sixth in the left axillary. On the twenty-third day the pulmonary lesions were resolving, but there was solid œdema occupying Scarpa's triangle on the right side and the right thigh and leg were very œdematous but soft. On the twenty-fifth day the œdema had diminished and the inguinal lymphatic glands were enlarged and painful. On the twenty-sixth day a seventh focus appeared at the left base and on the twenty-eighth day an eighth in the left subspinous region. On the thirty-second day the condition was grave; a line made on the skin with the nail was followed by a persistent red streak. A præ-laryngeal abscess containing pneumococci appeared. The inguinal glands were still enlarged. The blood contained pneumococci. In the evening a ninth focus was found at the left base. The respiration was difficult and the patient died on the following morning. The necropsy showed the left lung adherent to the thorax and extensively consolidated. The right lung was congested and œdematous. There was meningitis and the exudation contained pneumococci. The shoulder-joint was healed. Suppurative inflammation of the right psoas muscle was found. The presence of the pneumococcus in several of the lesions was verified by the fatal effects of injecting mice.

THE SANITARY STATE OF GERMAN EAST AFRICA.

FROM a report by Surgeon-Colonel Gartner of the German colonial army, which has been published in the *Archiv für Schiffs- und Tropen-Hygiene*, we learn that Bukoba on the Victoria Nyanza is the healthiest of the seventeen German stations in East Africa, whilst the least salubrious is Ulanga. As was to be expected, malaria was extremely prevalent during the period under report, the admissions to hospital due to this cause having amounted to 3360 per 1000 of strength among the white soldiers whose actual number was 122. In many of the cases the disease assumed a pernicious form and several of them proved fatal. Among the more numerous black troops, out of every 1000 admissions 887·9 were owing to ague, but the type was invariably mild. 21 cases of bilious hæmaturic fever occurred among the Europeans, 4 ending fatally. Quinine is said to have been the only drug which did any good in this disease. Arsenic was tried but its action was not satisfactory. As a palliative in the troublesome vomiting which usually accompanies the fever the tincture of iodine in from one- to four-drop doses sometimes acted like a charm. Dysentery and diarrhœa were comparatively innocuous; 23 Europeans and 174 natives were treated in the hospitals, chiefly for the last-named complaint. 14 white soldiers were admitted on account of acute rheumatism. This affection is common in Eastern Africa and often assumes a severe form with a tendency to cardiac complication and relapse. According to Surgeon-Colonel Gartner the sanitary condition of the colony, especially with regard to food, drinking-water, and habitations, leaves much to be desired, but some attempt has been made to dry up marshy places by planting palm trees. There are two chief hospitals in German East Africa, both of them being situated on the sea coast, at

Digitized by Google

Dar-es-Salaam and Lindi respectively. The report refers to the years 1894–95.

WORKING COLONY FOR INSANE EPILEPTICS.

THE Asylums Committee of the London County Council have decided on the formation of a working colony to accommodate 300 male insane epileptics. There are about 800 epileptic patients under treatment in the asylums under the control of the Council, and of these many are affected by a form of insanity which is remittent and during the intervals they are quite fit to undertake active employment. For such cases as these the colony will be a great boon. There are to be a medical officer and an assistant medical officer and an infirmary for the reception of patients during the periods when fits are severe or when mental alienation or excitement occurs. The colony is to be located on part of the estate of 1050 acres purchased for the erection of a new asylum at Horton, near Epsom, and the colonists are to be housed in detached buildings, each containing thirty-six inmates and three attendants. The arrangements have been planned on a liberal basis and appear to have been the result of wise consideration. We have no doubt that the colony will prove to be most helpful to the class which it is intended to receive, as the colonisation of sane epileptics has been at Chalfont and elsewhere. The work at the Chalfont colony appears to be seriously hampered for want of financial support, the committee not being able to provide the colony with a resident medical officer. It would seem to be an even wiser use of public money than that suggested by the London County Council if some were laid out on institutions similar to the one at Chalfont, where sane epileptics are taken with some hope that they may thus be saved from drifting into the class of insane epileptics.

FATAL SEWER-AIR POISONING.

ON Dec. 7th the Manchester City Coroner opened an inquest on the body of a corporation labourer who, together with a fellow workman whose body was not then but has since been recovered, was killed in one of the sewers by being "overcome by gas." The coroner said that the corporation had power to prevent anyone putting matter into the sewers which was likely to give off poisonous effluvia, that inquiries were being made as to the contents of this sewer in the City-road, and that a sample of the matter which was in the sewer where the men died was being analysed. Evidence of identification was taken and of the facts observed at the time. The foreman of the men said that he followed the two men into the sewer. There was a strong smell of gas which felt hot to the nostrils. It was stronger than coal gas and unlike it. In April last he smelt something like it in the same sewer but had not noticed it elsewhere. The two men went along the sewer, lighting their candles which burned brightly as they went. Witness called them back, saying, "It's too strong," and they answered, "All right, we're coming." He got out of the manhole and went to the next one to warn the man there. It was only after a long and dangerous search that the first body was recovered and on Dec. 7th the body of the second victim was found on the grid at the outfall of the sewage works at Davyhulme. The inquest was adjourned. These accidents being preventable ought not to occur and therefore seem the more deplorable. No doubt they will receive as they deserve the most serious attention of the corporation. Regulations might surely be made, and carried out, which would put a stop to them. The statement by the foreman implies that the smell was not familiar to him, so that it is probable the poisonous gas was derived from an unusual source, some industrial refuse or chemical residues.

ONE action of Lord Vernon whose death at the early age of forty-four years is announced from Bournemouth, has a particular interest not only for medical men but for all the country at the present moment. Lord Vernon spared no expense in his attempt to free the cattle on his farms from tuberculosis and last summer he invited a representative group of medical and scientific men to inspect the system of precautions which he had adopted at Sudbury Hall. The address delivered on that occasion to the assembled company by Professor Delépine will be found published in full in THE LANCET of Sept. 17th, 1898.

DR. H. D. ROLLESTON has been appointed physician to St. George's Hospital. Dr. Arthur Latham has been appointed assistant physician to the hospital in his place. Dr. Latham is assistant physician to the Victoria Hospital for Children, has held the offices of curator of the museum and medical registrar at St. George's Hospital, and was lately Radcliffe Travelling Fellow in the University of Oxford.

BARON FERDINAND DE ROTHSCHILD, the founder and supporter of the Evelina Hospital for Children, Southwark Bridge-road, built in memory of his wife, died suddenly on Saturday last at Waddesdon Manor. Like other members of his family the deceased Baron was a warm supporter of charities and especially of those which minister to the needs of the sick poor.

WE regret to announce the death of Dr. William Munk, Harveian Librarian of the Royal College of Physicians of London, from diabetes, at the advanced age of eighty-two years, on Tuesday last, Dec. 20.—Professor Alfredo Antunes Kanthack, Professor of Pathology in the University of Cambridge, died on Wednesday at the early age of thirty-five years. We shall publish obituary notices later of both gentlemen.

DR. ALFRED MILNE GOSSAGE has been elected Assistant Physician to the East London Hospital for Children and Dispensary for Women at Shadwell.

MR. CHAMBERLAIN has promised to preside at the dinner of the London School of Tropical Medicine to be held at the Hotel Cecil on May 10th, 1899.

BRISTOL HOSPITAL SUNDAY FUND.—The Mayor of Bristol, Mr. Herbert Ashman, presided at a meeting on Dec. 13th at the Guildhall in furtherance of this object. In moving the adoption of the report he stated that the sum received last year was only £1128 3*s.* 5*d.*, this being no doubt partly due to its being the first collection made by the Hospital Sunday Committee in places of worship, while only half the congregations joined in the combined effort. He hoped that in future the collection would be larger and more thoroughly taken up. The Rev. Urijah Thomas seconded the adoption of the report and it was carried. The Bishop of Bristol moved a resolution constituting the committee and spoke strongly in favour of the movement, personally undertaking to write to all clergymen of the Church of England who did not take part in last year's collection. Mr. F. R. Cross seconded the resolution and showed how uncertain the amount received from church and chapel collections had been in former years. The committee was then formed, the mayor being chairman, Mr. E. J. Swann honorary treasurer, and Dr. Bertram Rogers honorary secretary, with 23 other members, amongst whom were the High Sheriff, the Lord Bishop of Bristol, the Bishop of Clifton, the Dean of Bristol, Canon Cornish, the Rev. U. Thomas, the Rev. A. Thomas, the Rev. Dr. Glover, the Rev. A. Blatchford, Mr. F. J. Fry, and Mr. S. D. Wills.

QUACKS AND ABORTION:

A CRITICAL AND ANALYTICAL INQUIRY.

III.[1]

As the great majority of the people whose advertisements we have answered state or imply in their multicoloured pamphlets and circulars that amenorrhœa is a condition common to womanhood and that it is this condition of amenorrhœa so dangerous and so far-reaching in its evil effects that their different nostrums have been prepared to combat, it will be well, before going farther, to give the results of an inquiry into the causes which led 1000 women consecutively to present themselves at the out-patient department for obstetric cases of one of the large London hospitals.

Of 1000 cases seen at this out-patient department 183 patients had amenorrhœa. Of these 156 were pregnant and 12 were young girls at puberty in whom the condition of pregnancy was out of the question, so that of the 171 who might have been pregnant 156, or 96·5 per cent., were so. Of the remaining 15 cases 1 patient, aged twenty-seven years, single, had primary amenorrhœa; 7 patients (4 married and 3 single) had definite anæmia; 1 patient, single, had had pelvic peritonitis two years before and had seen nothing since; 1 patient, married, ? had approaching menopause; 1 patient, married, had fits and had seen nothing for seven years; and 1 patient, married, had seen nothing since before marriage some years ago. This leaves 3 patients, 2 who were married and 1 who was single, in whom there was no definite cause for the amenorrhœa.

It comes to this then. Of 183 cases 156 patients were pregnant, which accounts for their state of amenorrhœa. In 24 cases there was some definite condition in the age or history of the patient to render it unlikely that she was pregnant and in all these 24 cases such turned out to be the fact, while the amenorrhœa was dependent upon some easily ascertainable cause. It was no disease, but only the symptom of a physiological or pathological state; in some cases no medicine could have affected it and in none would the administration of emmenagogues have been right. In 3 cases only was there no definite cause present to explain the amenorrhœa.

It may be concluded: (1) amenorrhœa or irregularity of periods is common about puberty and at approaching menopause; (2) in otherwise healthy married or single women amenorrhœa in the great majority of cases is undoubtedly due to pregnancy; (3) where this is not the case with very few exceptions, only 3 out of the 183 cases of amenorrhœa met with in these 1000 cases, the condition of the patient or the circumstances under which the periods fail to appear are such as to render unlikely the possibility of pregnancy being the cause. At the hospital it would seem that the sufferer from amenorrhœa is either pregnant and knows it or is not pregnant and knows that she cannot be.

The fact that cases of amenorrhœa in healthy women where there is any doubt about the presence of pregnancy are so rarely seen in hospital practice indicates that such women do not seek hospital advice. The reason for this is probably twofold: (1) they guess that they are pregnant and know that a visit to the hospital will entail an examination which in the case of an unmarried woman might result in awkward revelations; and (2) they know that if the examination proves nothing yet that a missed period will be taken as an extremely likely symptom of pregnancy, while no such treatment as they often desire—viz., medicine to bring on the periods again—will be accorded them.

Seeing that the majority of instances in which healthy married women miss a period are cases of commencing pregnancy it is obvious that such a condition cannot be and is not as a rule productive of the ills ascribed to it by the vendors of quack nostrums; while, equally as a rule, to attempt to bring on menstruation in such cases is to attempt a criminal abortion.

The occurrence of amenorrhœa in cases of anæmia or other debilitating diseases such as phthisis is beneficial to the patient by avoiding any loss of blood and is a provision of nature to assist in arresting the progress of the diseases causing the condition. In these cases amenorrhœa, far from being an ill, is in fact an advantage to the patient.

We continue now an analysis of various pills and potions received in the course of this inquiry, with extracts of correspondence that has taken place with the vendors.

C.

We select two examples from a large number of recent advertisements bearing the same address which are now before us:—

Important to Ladies.—Especially to those who require an ABSOLUTELY CERTAIN and speedy remedy; a remedy which in thousands of cases has never failed to afford COMPLETE RELIEF, generally in a few hours, as Mrs. W. writes:—

"By adopting your treatment, my anxiety and misery was over WITHIN TWENTY-FOUR HOURS, although for three months I had been daily taking pills and other things in vain. HALF THE QUANTITY YOU SENT ME PROVED EFFECTIVE."

Full particulars will be forwarded to any lady on receipt of addressed envelope. The medicine is not expensive, as one bottle at 4s. 6d. is generally amply sufficient. By post 4s. 9d. A SWORN GUARANTEE accompanies all Testimonials. WRITE AT ONCE TO Mrs. B. B. F. ALLEN, 145, STOCKWELL-ROAD, LONDON, S.W.

To Ladies.—Especially to those who require a Safe and Speedy Remedy for all Irregularities, a Remedy which in thousands of cases has afforded COMPLETE RELIEF, generally in a few hours. No lady need despair, as the most obstinate and hopeless cases have been immediately relieved.

Mrs. J. states:—"I write to let you know I consider your medicine is fully worth £20 a bottle. I ONLY TOOK THREE DOSES before all was well. It has given me every satisfaction, particularly so because for over three months I had daily taken pills and other so-called remedies in vain."

The medicine is not expensive, as one bottle at 4s. 6d. is generally sufficient. By post 4s. 9d.

IMPORTANT WARNING.—This marvellous preparation HAS THE LARGEST SALE OF ANY FEMALE MEDICINE IN THE WORLD, a success achieved by MERIT ALONE. It is pleasant to take, perfectly harmless, but CERTAIN IN ITS ACTION, and readers are CAUTIONED against worthless and injurious imitations. Conclusive proof gladly forwarded to any lady on receipt of addressed envelope gratis and post free. It will cost you nothing, and SUCCESS BEING GUARANTEED, it may save you from a life of misery and bitter disappointment.

A SWORN GUARANTEE accompanies all testimonials and medicine. Write at once to Mrs. M., 145, Stockwell-road, London, S.W.

This is the firm which drew attention to itself last spring by an action which it brought against a newspaper called *Pick-me-up*, a report of which will be found in the *Times* of March 10th, 1898, under the title of Owen *v.* Greenberg. The newspaper had changed hands and the new proprietors found themselves saddled with a contract to insert Owen's advertisements, a series of which had been paid for in advance. This they declined to do and the nostrum vendor sought to recover the money he had paid in respect of the time during which his advertisements should have appeared and also damages for their non-insertion. The defendants paid money into court, denying liability and pleading that the advertisements were of an illegal and immoral nature. Mr. Justice Darling put the question so raised to the jury thus: "It was said that the advertisements were of an illegal and immoral nature and if the contract to insert them was of that nature the money the plaintiff had paid could not be recovered back. The question was, Was it intended by the advertisements to convey that the medicine would procure miscarriage or abortion? To procure abortion or to attempt, or counsel, or assist to procure it was a criminal offence and therefore you would expect any advertisement relating to it to be in very guarded terms. If the advertisement advised the taking of something for the purpose of procuring abortion it was undoubtedly forbidden by law." The jury found upon this question that the contracts for the insertion of the advertisements were immoral and judgment was given for the defendants.

In the evidence reported as having been given at the trial we note two or three points. Firstly, it was stated that the advertisements of the plaintiff were scattered broadcast through the press and appeared in any number of respectable papers: we regret to add to this that they have continued to appear in some papers ever since and that in spite of the jury's verdict in Owen *v.* Greenberg they were more numerous at the time when we commenced this inquiry than those of any rival firm. Various names and initials are used by the vendor but the address

[1] Articles I. and II. were published in THE LANCET of Dec. 10th and 7th, 1898, respectively.

Digitized by Google

in Stockwell-road as well as the wording of the advertisements establishes the identity. Secondly, Dr. D. H. Attfield, called on behalf of the defendants, informed the jury that he had analysed the compound sold by the plaintiff at 4*s.* 6*d.*, the alleged stronger mixture at 10*s.* 6*d.*, and the alleged strongest of all at 21*s.*, and that there was no difference between them on analysis. We may assume that Dr. Attfield's observation was perfectly accurate, for it remained unchallenged. We have ourselves analysed the stuff sold at 4*s.* 6*d.* and we append the analysis. Thirdly, we are unable to extract from the report of Owen *v.* Greenberg the plaintiff's testimony as to his trade, for he did not go into the witness-box in support of his case.

Our letter to the Irristum Company, for that seems to be the name principally used by Mr. Owen, or Allen when once his customers get into communication with him, enclosed 4*s.* 9*d.* for a bottle of mixture and postage, requesting that it might be packed so as to be safe from observation, the sender being represented as a maid-servant. In reply we received a bottle of the Irristum medicine, a large bundle of printed matter, chiefly consisting of testimonials of the usual description, and also a lengthy dissertation on the merits of Irristum containing the following passage: "*Irristum gives rise to no nausea*, its beneficial effects are *almost at once apparent* and the lady who has the confidence to employ it as an agent finds that her domestic associations and the pleasures of social life are not interfered with but distinctly enhanced."

We have referred already to the probability of women buying compounds advertised in such terms as those of the Irristum Company without further question for the purpose of procuring abortion. In our dealings with the Irristum Company they denied treating pregnancy when pressed upon the subject and recommended the writer who asked in terms for an abortifacient to "consult a medical man," which seemed to us a fairly impudent suggestion. But surely any question of "Mrs. W.'s" grateful testimonial (see the first of the two advertisements printed above) or of the similar testimonials quoted by the Irristum Company having reference to amenorrhœa and dysmenorrhœa apart from pregnancy is practically disposed of by the figures we have given as to the frequency of these conditions. The inevitable dilemma is that either Irristum medicines, in spite of the virtuous intent of their proprietor, are swallowed by pregnant women or that the testimonials are bogus.

Analysis of ALLEN'S MIXTURE (KNOWN AS "IRRISTUM").

Specific gravity, 1066.
Water, 82·67 per cent.
Chloroform, 1·66 per cent.
Organic substances, 14·94 per cent.
Mineral matters, 0·73 per cent.

As will be seen, this preparation contains an odd constituent in the shape of chloroform. The relatively high density of the fluid was due to sugar. The colouring matter was cochineal, the fluid turning a brilliant cochineal colour when ammonia was added. The liquid exhibited a marked acid reaction and was acrid to the taste. Chloroform extracted an extremely bitter yellow substance which with chemical reagents behaved exactly like extract of colocynth. The mineral matter, which is small in amount, contained an unimportant quantity of iron. A search for arsenic and mercury was followed by negative results.

D.

The advertisement in this case was as follows:—

EVERY WOMAN

Should send two stamps for our 32 page Illustrated Book, containing valuable information how all Irregularities and Obstructions may be entirely avoided or removed by simple means. Recommended by eminent Physicians as the only Safe, Sure, and Genuine Remedy, Never Fails. Thousands of Testimonials. Mr. P. BLANCHARD, Forest-road, Dalston, London.—Advt.

We wrote asking for the work advertised and received a bundle of pamphlets and leaflets, two being in book form. Of these two one was filled chiefly with testimonials lauding the medicines which we afterwards ordered; the other was an elaborately illustrated catalogue of rubber preventives and similar appliances. The book of testimonials was illustrated also with pictures of husbands and wives delighted with the results of Mr. Blanchard's remedies and the testimonials themselves were of the usual kind; one, for instance, ran as follows:—

DEAR SIR,—I had the greatest trouble in persuading my wife to try your remedy, because she had tried so many without avail when at last I induced her to *and the fourth dose* proved effective; you can imagine her joy and surprise. 7*s.* 6*d.* is cheap; it is worth 20 times that amount. —— DURHAM.

The medicine advertised consisted of "No. 1 Mixture and Pills" and "Special Mixture and Pills," termed also "P.B. Mixture and Pills," the latter stated in large capitals to "Act Like Magic." On an order form sent among other papers we find the following notice or intimation:—

The powerful and certain action of our Medicine necessitates the Warning that it should not be taken by those expecting to become Mothers, as it is sure to produce a miscarriage.
This Order is accepted on the basis that the purchaser is not *enceinte*.

We can only say with regard to this that without using any order form we wrote a letter asking for "a bottle of Mixture and Extra Strong Pills," these being the words of one of the circulars, enclosing at the same time 7*s.* 6*d.* This letter distinctly stated that the writer believed herself to be pregnant and the mixture and pills of which we now give the analysis were sent in response.

Analysis of MR. P. BLANCHARD'S MIXTURE.

The analysis of this fluid was as follows:—
Water, 98·13 per cent.
Organic matters, 1·25 per cent.
Mineral matter, 0·62 per cent.
The mineral matter consisted almost exclusively of iron.
The fluid on evaporation evolved a very marked smell of nutmegs. No satisfactory results were obtained on applying the tests for aloes and rhubarb. The specific gravity of the fluid was 1011, a result which is in accordance with the small amount of dissolved substances present. The analysis in brief indicates that the mixture is simply a feeble solution of nutmegs and iron. Arsenic or mercury could not be found.

Analysis of MR. P. BLANCHARD'S PILLS.

These pills were pink coated, the coating consisting of a talc-like substance.
Moisture, 13·00 per cent.
Organic substances, 48·28 per cent.
Mineral matter, 38·72 per cent.
The mineral matter was nearly pure oxide of iron.
Alcohol extracted a dark resinous compound possessing a bitter taste and yielding reactions characteristic of commercial Socotra aloes. The pills contained no arsenic or mercury.

E.

We took this advertisement as an example in our first article:—

Ladies, Consult Madame Wood, LADY SPECIALIST ON ALL FEMALE AILMENTS, IRREGULARITIES, AND OBSTRUCTIONS, however obstinate. Save Time, Trouble, and Expense by consulting an Experienced Specialist AT ONCE. My Remedies are the most powerful and strongest on earth, effectual after all others have failed. May be taken by the most delicate. A lady writes: "NONE HAVE EVER DONE ME ANY GOOD BUT YOURS, NOTWITHSTANDING THEIR SO-CALLED TESTIMONIALS." Madame Wood may be consulted daily, or by letter, enclosing stamped envelope. Price of Mixture 4*s.* 6*d.*, extra strong 11*s.*, secretly packed. By post 3*d.* extra. 20, GREAT AVENHAM-STREET, PRESTON, LANCASHIRE.

Our letter ordered a bottle of the extra strong mixture, enclosed 11*s.* 3*d.*, described the sender as a servant in a situation, and asked for the bottle to be secretly packed as advertised. We received a bottle from Preston and we note that the desire for secrecy extended to the sender, for the letter which accompanied it bore neither date nor signature, while the bottle also had nothing on it that would in any way identify the person responsible for its contents. It was labelled, "The mixture, a teaspoonful three times a day." The letter was as follows:—

DEAR MADAM,—Yours to hand enclosed find Mixture, take before meals. I shall be pleased to hear if the mixture effects a cure, *if not* you better send full particulars & I shall be pleased to advise you further, in most cases it is just a matter of a little perseverance, some people require more medicine than others, when you write again mention what paper you have seen it in.

A subsequent letter stating, in reply to the request for particulars, that the sender had been *enceinte* for four months was not replied to by Madame Wood and we did not press the matter. We append the analysis of her 11*s.* medicine. It bore no Revenue stamp.

Analysis of MADAME WOOD'S MIXTURE.

Specific gravity, 1015.
Water, 98·83 per cent.
Organic substances, 0·69 per cent.
Mineral matters, 0·48 per cent.

Digitized by Google

This preparation did not appear to contain any iron, the mineral matter consisting of alkaline carbonate. The original fluid was distinctly alkaline and in appearance precisely like a boiled alkaline solution of rhubarb.

Subsequent extraction with ether gave a brilliant yellow residue responding satisfactorily to the reactions of rhubarb. Our examination indicates, therefore, that this mixture is a weak alkaline infusion of rhubarb. On testing for aloes the results gave no certain positive indications. There were no poisonous metals present.

F.

This person does not require much comment; the advertisement was a follows:—

Dean's Female Mixture. Is positively the only reliable, and strongest on earth. It will not harm the most delicate. It will cure the most obstinate cases within twelve hours. Success guaranteed in every case however long standing. THOUSANDS OF GENUINE TESTIMONIALS. Price 2s. 9d., post free 3d. extra. To be had only of C. DEAN, MEDICAL HERBALIST, 113, GRAY'S INN-ROAD, LONDON, W.C.

It will be noted that there is no phrase that can be construed as a reference to menstrual troubles excluding those arising from pregnancy. In fact there is no direct reference to anything at all. It is "a female mixture": "the strongest on earth": "success guaranteed in every case." The nature of the case and of the success guaranteed is left entirely to the reader to determine. Our letter to C. Dean asked for a bottle of the mixture at 2s. 9d. and was practically the same as that sent to Madame Wood and others. We received a bottle in reply with the following printed letter:—

C. Dean, Medical Herbalist, 113, Gray's-inn-road, Holborn, W.C.

MADAM,—Enclosed you find the Female Mixture. Take the contents of the bottle in two doses: one half at night, and the other half on the next morning. If no relief you will have to take six doses of a Stronger Mixture, of which the price is Five Shillings and Sixpence. Relief is certain. Do not lose time.

Yours truly, C. DEAN.

We did not try the stronger mixture. The analysis of that at 2s. 9d. is as follows:—

Analysis of MR. C. DEAN'S MIXTURE.

Specific gravity, 1050.
Water, 94·13 per cent.
Organic substances, 0·35 per cent.
Mineral matter, 5·52 per cent.

The mineral matters consisted entirely of sulphate of soda and of iron and we infer that the mixture consists in the main of a solution of Glauber's salt and iron. Poisonous metals could not be traced.

G.

The advertisement in this case was as follows:—

FREE! — MARRIED LADIES! — INFORMATION and ADVICE of PRICELESS VALUE. Send stamped envelope. Mention this paper.—Mrs. LAWRENCE, 2, South John-street, Liverpool.

In reply to our stamped envelope we received various advertisements and eventually wrote again enclosing money with a definite statement that the sender believed herself *enceinte* and asked for a "bottle of Special Strong Mixture at 12s. 6d. and a box of Special Corrective Pills at 2s. 9d.," for which were enclosed a postal order for 15s. and 3 stamps. The goods arrived accompanied by a memorandum or invoice which we reproduce, while we append the results of our analysis below:—

From Mrs. LAWRENCE, the Ladies' Specialist and Confidante, Inventress of Domestic and Surgical Specialities, Malthusian Appliances, &c., 2, South John Street, Liverpool, and 3, St. Elmo Rd., Egremont, Liverpool.

DEAR MADAM,—Thanking you very much for your kind order, Mrs. Lawrence now has pleasure in handing you, herewith, her WORLD FAMOUS OBSTRUCTION REMEDY, to the value of your remittance, and she trusts that it will Prove Successful as speedily in your case as it has Done Generally. Assuring you that in no event will your name be published without your permission. Mrs. L—— hopes that you will be good enough to let her know the result, at your earliest convenience, and would strongly advise you to have plenty of out-door exercise, (keeping yourself free from colds), and a Hot Foot-Bath at night, whilst taking her remedy.

Analysis of MRS. LAWRENCE'S MIXTURE.

Water and oil of peppermint, 93·59 per cent.[2]
Organic substances, 4·60 per cent.
Mineral matter, 1·81 per cent.

[2] Equals loss on evaporation.

The mineral matter consisted chiefly of iron, sulphate of soda, and some alkaline carbonate.

The specific gravity was 1030.

This proved to be a very complex mixture. It was a treacly, dirty brown fluid with a strong taste of peppermint. On distilling away the peppermint oil the residual fluid possessed a bitter taste and at the same time a flavour strongly suggestive of liquorice. Alcohol extracted a substance tasting exactly like liquorice. Ether dissolved a yellowish green substance closely resembling apiol as regards appearance and smell. The odour of myrrh in this residue was unmistakable. Feeble reactions were obtained corresponding with those yielded by Socotra aloes. The preparation is compounded of apparently a hybrid of the mistura ferri co. and the decoctum aloes co. of the Pharmacopœia. There was no evidence of mercury or arsenic.

We shall next week continue and possibly conclude our analyses of the various pills and potions for which we applied.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

THE SUPPORT OF THE PRINCE OF WALES.

A PRIVATE meeting was held at Marlborough House on Dec. 20th, under the presidency of the PRINCE of WALES, to further the objects of the National Association for the Prevention of Consumption.

At the invitation of His Royal Highness there were present: The Marquis of Salisbury, Lord Rosebery, the Earl of Derby, Lord James of Hereford, Sir Samuel Wilks (President of the Royal College of Physicians of London), Sir T. Grainger Stewart (President of the British Medical Association), Mr. T. McKinnon Wood (Chairman of the London County Council), Lord Loch, Mr. Wernher (of the firm of Messrs. Beit and Wernher), Dr. J. W. Moore (President of the Royal College of Physicians of Ireland), Dr. J. Andrew (President of the Royal College of Physicians of Edinburgh), the Chief Rabbi, Sir James Blyth, Sir Richard Thorne, Mr. Walter Long (President of the Board of Agriculture), Dr. Thomas Barlow (physician to Her Majesty's Household), the Lord Provost of Edinburgh, the Director-General of the Medical Department of the Navy, the Director-General of the Army Medical Service, Mr. Shirley Murphy (medical officer to the London County Council), Dr. Grimshaw, Dr. Clement Godson, Sir William Priestley, M.P., Dr. Howship Dickinson, Dr. Playfair, Dr. Hermann Weber, Dr. J. E. Pollock, Dr. Woods, Sir John Brunner, Dr. Sidney Coupland, Sir James Sawyer, Mr. S. Neumann, Canon Rawnsley, Mr. James Knowles, Mr. E. Hulse, Mr. T. Mark Hovell, Sir Donald Currie, Mr. Bischoffsheim, and the members of the Organising Committee as follows: Sir William Broadbent, M.D. Lond., F.R.S. (chairman), Mr. Malcolm Morris (hon. treasurer), Dr. StClair Thomson (hon. secretary), Sir George C. W. Brown, Sir James Crichton Browne, M.D. Edin., F.R.S., Sir Ernest Clarke, Professor Corfield, M.D. Oxon., Dr. F. W. Burton-Fanning, Dr. Alfred P. Hillier, Dr. Constantine Holman, Professor John McFadyean, M.B., C.M. Edin., Dr. Isambard Owen, Dr. Vivian Poore, Mr. A. W. Mason (the President of the Royal College of Veterinary Surgeons), Dr. Arthur Ransome, F.R.S., Mr. C. Rube, Professor Burdon Sanderson, M.D. Edin., F.R.S., Mr. Frederick Treves, Dr. Dawson Williams, and Dr. Theodore Williams.

The PRINCE of WALES opened the proceedings by calling on Sir WILLIAM BROADBENT, chairman of the organisation, to deliver a statement on the work of the association.

Sir WILLIAM BROADBENT said:—May it please your Royal Highness, I have the honour to lay before your Royal Highness on behalf of the Organising Committee of the National Association for the Prevention of Consumption a brief statement of their objects and methods.

We learn from the returns of the Registrar-General that nearly 60,000 deaths are every year registered as due to tuberculosis in England and Wales alone, and to this number may be added a considerable percentage of the deaths set down to acute affections of the lungs in which tubercle has played an unrecognised part. Of these over 40,000 are from consumption, 6000 from tuberculous disease of the intestines and mesenteric glands, and 6500 from tuberculous meningitis. The destructive work of tubercle does not end here; 5500

Digitized by Google

deaths are attributed to other forms of tuberculosis, among which are diseases of the bones. Hump-back, hip-joint disease, disease of the knee, ankle, elbow, wrist, and other joints which cripple or disable so many children are the sign manual of tubercle.

This terrible waste of life with all the protracted suffering attending it and the distress, moral and material, which it involves is in great measure preventable. Already by the effects of subsoil drainage, by improved hygiene, by the higher general standard of comfort and cleanliness, by greater attention to ventilation and to the construction of dwellings, the number of deaths from consumption and other forms of tuberculosis has been reduced by more than 50 per cent. in fifty years. The single sad exception to this statement is that tabes mesenterica, the disease of the bowels in children traceable to tubercle conveyed by milk, has increased.

But while sanitary improvements have so far reduced the mortality from tuberculous diseases science has pointed out the way by which these ravages may not only be indirectly mitigated but directly prevented. It is now definitely known that consumption is a contagious disease, that it is communicated from person to person and from animals to man, and that it arises in no other way. It is not an inherited vice in the constitution which declares itself in course of time, but while some constitutions are more prone to it than others and while an unhealthy mode of life and unwholesome surroundings predispose to its attacks, every case of consumption is derived from some pre-existing case.

Phthisis with all the various forms of tuberculous disease is the work of a microbe—the tubercle bacillus discovered by Koch. This living organism is present in countless millions in the diseased lungs or intestines or bones. By its multiplication it blocks the minute blood-vessels, chokes the air vesicles, and destroys structures and by a poison or toxin which it forms it gives rise to febrile disturbance, nocturnal perspirations, and wasting. It is by transmission of these bacilli that tuberculous diseases of all kinds are spread.

The principal way in which they are conveyed from a diseased to a healthy person is by means of the expectoration which contains them in enormous numbers and which when dried is suspended in the atmosphere, especially of ill-ventilated rooms, in the form of dust and inhaled. Happily they are not present in the breath of the consumptive patient so that consumption is not contracted merely by breathing the same air or living in the same house with a sufferer.

Another way in which the bacilli are disseminated is in milk. Cows, unfortunately, are very subject to tuberculosis and sooner or later the bacilli find their way into the milk. Through milk so contaminated infants and young children become affected with tabes mesenterica, tuberculous meningitis, and diseases of the bones.

The flesh of diseased animals also may contain the bacilli.

If we could ensure the destruction of all the sputa of the sufferers from phthisis and secure a supply of milk and meat absolutely free from tubercle bacilli all the diseases due to tuberculosis which now cause one-seventh or one-eighth of the total number of deaths would cease from the land.

These facts are generally known throughout the medical profession and the precautions based upon them will be inculcated by the medical attendant. But the adoption of the nceessary measures would, as we know from abundant experience, be very slow and would require many years, and if 70,000 persons die every year from tuberculous disease, which for Great Britain and Ireland is a very moderate computation, at least 200 new persons must catch the disease every day. It is the realisation of this fact which has called into existence the National Association for the Prevention of Consumption and Other Forms of Tuberculosis. The mission of the Association is to carry into every dwelling in the land an elementary knowledge of the modes in which consumption is propagated and of the means by which its spread may be prevented and thus to strengthen the hands of medical men throughout the country who are dealing with individual cases of this disease. To this end the public attention must be captured, the public imagination must be impressed, the defensive instincts of the general public must be aroused, and we do not hesitate to express our belief that your Royal Highness will by the single gracious act of calling together and presiding over this meeting save thousands of lives.

The objects of the Association can be stated in a few words. They are (1) to educate the public as to the means of preventing the spread of consumption from those already suffering from the disease; (2) to extinguish tuberculosis in cattle; and (3) to promote the erection of sanatoria for the open-air treatment of tuberculous disease.

It is only necessary here to indicate the spirit in which the operations of the society will be conducted. While making known the contagious character of consumption it will endeavour to allay the panic which arises in some minds when it is known that consumption is catching. It does not advocate the compulsory notification of consumption but it will urge upon sanitary authorities the desirability of insisting on the disinfection of rooms in which consumptive persons have died when notification of the fact is made through the certificate of death. Its method is instruction and persuasion, not compulsion. In particular it will seek to enlist the coöperation of the sufferers themselves, and when the victim of consumption understands that by observing the precautions recommended by the association he or she is protecting family and friends from the disease he or she will be careful to carry them out. On the other hand, the friends and relatives of sufferers and the public generally will in self-defence discourage and repress the filthy and unnecessary habit of expectoration in public vehicles and places of public resort, and we may expect railway companies and others to follow the example set in America of putting up notices pointing out the danger of the practice.

So again with regard to milk. The society recognises the fact that it is impracticable to stamp out tuberculosis in cattle by the immediate slaughter of all diseased animals, but it will insist that the public has a right to a milk-supply which shall be absolutely free from tubercle bacilli and shall not scatter death among the children of all classes of the community. It will earnestly advocate the testing of herds by tuberculin and the isolation of animals found to be affected, a method which has been attended with conspicuous success in Denmark, and it will urge upon district and county councils and all rural and urban authorities the supervision of cattle-sheds and of dairy farms and of all the agencies for the distribution of milk.

Another important matter upon which it has already memorialised the London County Council is the provision of public slaughter-houses where the inspection of carcasses can be carried out before the evidences of diseases have been removed.

Until tuberculosis is eradicated from among our cattle an indispensable precaution is to boil or sterilise all milk, especially that given to children. The sterilisation of milk is an easy and simple process and it ought to be done at home. Sterilisation on a large scale at the dairy is open to abuse and it may be so carried out as to impair the nutritive qualities of the milk.

The third great object of the association is the promotion of the erection of sanatoria for the open-air treatment of consumption and tuberculous disease generally. It aims not only at prevention but cure. The isolation and cure of those suffering is, however, the very best and most efficient preventive measure, since a consumptive patient once lodged in a sanatorium ceases to be a focus from which the disease spreads.

Your Royal Highness has visited Falkenstein and can bear witness to the provision there made for the open-air treatment of phthisis and of the success which attends it. Your Royal Highness may therefore well reproach us for lagging behind Germany in a matter of such importance. America also is in advance of this country, but it is only lately that the medical profession here has been convinced that the open-air treatment of consumption could be successfully carried out in this country. We have thought it necessary to send out patients on long voyages or to the South of France or to the germ-free atmosphere of the high Alps originally recommended by Dr. Hermann Weber, one of the pioneers in the hygienic treatment of consumption, who is here as a guest of your Royal Highness to-day. Now, however, experience gained in such diverse parts of the country as Edinburgh, Norfolk, and Ireland, to say nothing of the different winter resorts on the south coast, has demonstrated that most satisfactory results can be obtained at home. The chance of recovery, formerly the privilege of the favoured few, is thus open to all classes of the community. The Association, therefore, will advocate the erection of sanatoria for every large centre of population. The Poor-law authorities will sooner or later find that it is more economical to provide sanatoria where tuberculous paupers may recover than to send them to infirmaries to die. Municipalities will consider it their duty to defend the populations over whose interests

Digitized by Google

they watch from consumption as they now do from fever by the erection of sanatoria. And above and before all the charitable public generally and those whose sympathies are drawn towards sufferers from consumption by having lost parents, or children, or brothers, or sisters, or friends from this disease, will seize the opportunity of doing more for them than merely to smooth their passage to the tomb.

Meanwhile a beginning is to be made in London by a self-supporting sanatorium which will minister to the needs of the class which lies between the rich and the poor. The London partners of Messrs. Wernher and Beit have undertaken to erect and equip such a sanatorium at an estimated expense of £20,000, the construction and management of which will be under the guidance of the Association. As at Falkenstein any excess of income over expenditure will be devoted in the first instance to the payment of a small interest (2½ per cent.) on the capital and the balance to such purposes in connexion with the objects of the Association as may be determined by the committee.

This offer has been a great encouragement to the Organising Committee and we know that many benevolent persons are ready and waiting to come forward to supplement it by making provision for the poor.

The idea which animates the Association is that the prevention of consumption is a national duty in which the medical profession and the public can coöperate, the medical profession leading and guiding the movement. The Organising Committee have every reason to congratulate themselves on the interest which has been excited in all parts of the country. Branches are being formed in York, Norwich, Ipswich, Huddersfield, and other towns, and at York a considerable sum of money has already been raised for the erection of a sanatorium.

The impetus given to the work of the Association by the meeting here to-day under the presidency of your Royal Highness will greatly expedite the success of the Association in dealing with the gigantic task which it has undertaken.

Sir T. GRAINGER STEWART said: Your Royal Highness, I owe the honour of being asked to join this meeting to the fact that I am President of the British Medical Association and also occupy the chair of medicine in the University of Edinburgh. I speak in the name of the profession as represented by the Association and the Edinburgh School of Medicine also. I should congratulate the profession chiefly upon the fact that you, Sir, have been graciously pleased to summon this meeting. I congratulate the National Association for the Prevention of Consumption and also the profession upon the effective and luminous statement made by Sir William Broadbent in opening the discussion. I venture to say with regard to Scottish experience that there are two or three points worthy of notice. In the first place statistics show that Scotland is very much in the same position as England and Wales as described by Sir William Broadbent. I find on looking at the returns for 1896 that about 173 out of every 100,000 of the whole community died from pulmonary consumption; in Edinburgh about 170 per 100,000 died; in Glasgow the numbers are 192; and in Scotland generally 166. Thus in Scotland we are deeply interested in the question and have already had a good deal of attention directed to it. As a matter of fact evidence given before the Royal Commission shows that some of the dairy farmers in the neighbourhood of Edinburgh have made costly experiments. One who found on testing his herd of 34 milch cows that 64·4 per cent. of them were tuberculous set aside these in a separate place and did not use them for milk for supplying his customers. He replaced the animals and now he is able from an absolutely sound and safe herd to supply a milk which may be safely used without being sterilised or boiled and which is more pleasant to take and more safe for the community. He finds he gets a higher price for his product. We shall soon have many dairies absolutely safe in these respects. Another point with regard to Scottish experience which may interest your Royal Highness is that experiment with the open-air system has been fairly tested and carried out near Edinburgh. You, Sir, have visited Falkenstein—I do not pretend that the slopes on which the Victoria Hospital for Consumption stands compare with the splendid slopes of Falkenstein, but they have brought out results which have been astonishing. It is proved that in that hospital both night and day the windows can be kept widely open not only without injury but with positive advantage. I have seen patients leave my own wards in the Royal Infirmary to be treated there by the open-air treatment in a climate not famous for its clemency and these patients have improved rapidly and splendid results have been attained. Not only has this work demonstrated the success of the open-air treatment, but it has sufficed to diffuse a great deal of information.

Dr. MOORE (President of the Royal College of Physicians of Ireland) said: I wish to express my acknowledgment of the compliment which is paid to my College in asking me to address a few words to this meeting. For my facts about the prevalence of consumption in Ireland I have to thank the Registrar-General for Ireland, Dr. Grimshaw. In the twenty years ending 1890 there were registered 1,800,000 deaths and of this in round numbers 200,000 were caused by consumption of the lungs alone. If we add to that terrible list of deaths the forms of consumption which kill in other ways than through the disastrous effects upon the lungs we find that tuberculosis was responsible for 11·2 per cent. of all the deaths. It is a remarkable fact that all the so-called zymotic diseases put together have not killed as many in Ireland as this one fell scourge of the human race, tuberculosis. It must be admitted by all hospital physicians that tuberculosis is a disease which is not best treated in our general hospitals. The surroundings are not the best for the consumptives themselves; there is a pathos about a hospital ward injurious to anyone seriously ill. Further, the consumptive patients have an injurious effect upon the others. In Ireland we have made a good start at treatment in special sanatoria. There is a magnificent hospital in Belfast—the Royal Hospital. We have also built a series of hospitals—one a convalescent hospital, one for children, and the third for consumptives—but funds unfortunately only admit up to the present of opening ten beds. Through the generosity of Earl Fitzwilliam some years ago a plot of ground in the county of Wicklow extending over nineteen acres was given free of rent for the purpose of the construction of a consumption hospital. It started into existence under the loving patronage of the Marchioness of Zetland. It was opened on March 19th, 1896, for the reception of 24 consumptive patients, 12 male and 12 female. The treatment adopted is the open-air treatment; the place lies midway between the sea and the mountains and its climate has been tested by observations taken for the last year and a half. Since opening the patients treated have been 200 in number. Of 164 patients who were discharged 2 died. The remaining 162 made an average gain of half a stone in weight. Many of the early patients have been at work since they left and some appear to be perfectly well according to their friends. That last statement I have personally corroborated. There is a point on which I have not yet made up my mind and that is the question of notification. If consumption is made notifiable it will be necessary to establish some machinery properly supervised by medical officers, and I am sorry to say that from some oversight the Local Government Bill for Ireland contains no provision for the establishment of county medical officers. A magnificent machinery exists in the country for teaching the people the danger of tubercle, and we owe it to Her Majesty the Queen who, with the womanly instinct for which she is loved, eleven years ago devoted a large sum of money for the purpose of providing nurses for the sick poor in their own homes. These nurses know all about the danger of tuberculosis and as they go to the homes of the sick poor in the cities and in the country can tell the people how dangerous contaminated expectoration is and how necessary it is to test the milk.

Sir JAMES SAWYER pointed out that in the arrest of other infectious diseases which have been successfully prevented the chief motive power has not been legislation but popular knowledge.

Dr. J. ANDREW (President of the Royal College of Physicians of Edinburgh) said that he supported all that Sir Grainger Stewart had put forward.

Professor MCFADYEAN said: In every animal that has the scourge of tuberculosis there are certain parts that contain the living germs of the disease and no fact is more firmly established than that any human being who takes such parts of an animal as food runs the risk of contracting the disease unless cooking or some other process can be relied upon to kill the germs. A very few years ago a more alarming estimate than is indicated by what I have just said was widely entertained because it was held by many that in the majority of tuberculous animals the germs were found in the whole body and no tuberculous carcass was fit for food. This is not borne out by recent investigations. We know now that in the tuberculous animal there are some parts containing the tubercle, but the greater part does not contain

Digitized by Google

germs and is not dangerous. That was the finding of both the Royal Commissions which have sat on the subject. But while recent investigation has thus shown that the danger is not so great as it was at one time supposed to be, the knowledge that we have recently acquired tends in quite the opposite direction. Speaking generally the individual animal is less dangerous, but there are far more animals dangerous to a certain degree than was suspected a few years ago. It is probably true of this country and all over the continent that not less than 20 per cent. of cattle sold for food are tuberculous. Tuberculosis, as Sir William Broadbent has remarked, is a common disease in milch cows and in a considerable proportion of milch animals affected by tuberculosis the disease attacks the udder and the milk is thus affected. There may be nothing about the milk to warn the individual who sells it, or the more unfortunate individual who drinks it, of its dangerous character. It is impossible to doubt, indeed we know as a matter of fact, that there is scarcely any legal obstacle to the selling of such milk. It is being sold every day and some human beings are being infected daily. When measures are devised for the safety of human beings the question of tuberculosis among animals must be taken into consideration. This Association may render great service by diffusing the knowledge that until tuberculosis can be eradicated from our domestic animals everyone can protect himself by thoroughly cooking meat and milk.

The Marquis of SALISBURY said: Your Royal Highness, Lords, and Gentlemen,—Sir William Broadbent has placed in my hands a resolution which he has desired me—nay, he has almost prescribed it to me—to move, and in these days of advancing democracy the only authority left is the authority of your doctor; otherwise I should have demurred to his request because I am unfit to comment upon this most important subject, the object of the present meeting, and I feel very unworthy to do so after the distinguished authorities who have given us the benefit of their opinion. I believe that it is true, as Sir William Broadbent says, that we are very much behind the world in these matters. We are behind the world in practical efforts. We are even behind the world in theories of the matter, for I believe it is quite a recent event that the contagious character of consumption has been fully acknowledged in this country. It is the public only who can effect a change and it is only by public knowledge that any real good will be done. Nothing has seemed to me more striking in the luminous statement of Sir William Broadbent or in the discussion following than the absence of all desire that the powers of the law should be brought into operation to carry out the objects of the Association. It is a snare which they should carefully avoid. They must be content with preaching the salutary doctrine which they hold and must not think of applying to the secular arm. Without alluding to any vexed questions we know that there are some difficulties which are attached to the carrying out of the decrees of medical science by the action of the law and the danger of any similar result would be very great in the present case. I see my right honourable colleague the Minister for Agriculture here and I speak, so to say, under his eye, but he will join me in saying that it would considerably prejudice the spread of sound opinion upon this subject if any attempt were made to procure or ensure sanitary conditions by any action of central or local authority. It must be taught; it cannot be enforced. I am afraid if you attempted to enforce the use of tuberculin, which has been referred to, you would find among the farmers many conscientious objectors who would object to the operation of your law. Let us be warned by past mishaps and I have no doubt that under the patronage of His Royal Highness, with the unequalled facilities which the medical profession has for spreading sound ideas on scientific matters among the population all over the country (through the machinery of nursing associations, by literature, by the action of the scientific missionaries who now spread themselves all over the country), you will be able to produce a sufficient recognition. The dangers of which science now warns us must be guarded against and in some years hence, and I have no doubt at an early period, when you have generated such a movement as this, the extinction to a very great extent of this terrible disease will come about. Great progress has already been made. There is, however, still much to be done. Whether it is done rapidly or slowly or whether it is done effectively or imperfectly will depend on the energy with which this Association labours at the work and especially on the assistance received from the medical profession. I will now propose the resolution which is as follows:—

This meeting desires to express its approval of the effort which is being made by the National Association for the Prevention of Consumption and other Forms of Tuberculosis to check the spread of the diseases due to tubercle and to promote the recovery of those suffering from consumption and tuberculous disease generally. It also commends the method adopted by the Association of instructing public opinion and stimulating public interest rather than the advocacy of measures of compulsion.

Sir SAMUEL WILKS said: I beg leave to second the resolution. The subject of tuberculosis in the form of consumption has received so much attention during the last few years with reference to its spread and its dangers that we think now we ought to receive the coöperation of the public in order to endeavour if not to suppress, at any rate to withstand, its ravages. As Lord Salisbury has just said it is only as recently as the past generation that this was looked upon as a kind of scourge hanging over the country. It is only of late years—I should think it was first due to increased means of locomotion when people could easily get out of this country, especially in winter time—that we were able to get air and sunshine for our patients, but they were only the richer people in the land. Some went to the Riviera, to the Engadine, to the Cape for the sea voyage and they came back cured. Not only is this so in my own medical experience, but in friends and gentlemen in my own profession I could count dozens of cases of men who have passed through life after being thus cured of consumption. This opinion has been strengthened from experiments made on the tubercle bacilli. It is found that if these are cultivated artificially in damp places they grow but that in sunshine they die. This is all corroborative of what I have said. I am told there is a remarkable illustration of this in the Zoological Gardens. There the idea used to be to keep up a high temperature in the houses of certain animals from the tropics; now they let these animals go out in the winter time into the fresh air and the mortality is considerably less. It might be said if all this is known that the patient could go to the doctor and he could get his prescription; but the prescription is a dear one, an expensive one. A poor clerk comes to you and you order him six months or twelve months abroad; he cannot afford it and he cannot do it. We want these sanatoria to place persons under the best conditions for what they specially require and these are sunlight and air. When I was at school I used to read about Diogenes in his tub who, when visited by Alexander the Great said, "Get out of my sunshine." I thought that was rude and ill-mannered until five years ago when after I had had influenza I went to the seaside for air and sunshine and as I sat there in front of the sea a friend came before me and I said, without thinking of Diogenes, "Get out of my sunshine," and then for the first time I saw what a great philosopher that man was. I look upon this movement, Sir, as a national object and the proof of it is in the meeting here under your auspices, because with your discrimination you would not have undertaken this unless you had considered it a national object.

H.R.H. the PRINCE of WALES said: As chairman I have to read to you the resolution so ably moved by Lord Salisbury and seconded by the President of the Royal College of Physicians; it is as follows:—

This meeting desires to express its approval of the effort which is being made by the National Association for the Prevention of Consumption and other forms of Tuberculosis to check the spread of the diseases due to tubercle and to promote the recovery of those suffering from consumption and tuberculous disease generally. It also commends the method adopted by the Association of instructing public opinion and stimulating public interest rather than the advocacy of measures of compulsion.

The resolution was carried unanimously.

The Earl of ROSEBERY, in moving a vote of thanks, said: My Lords and Gentlemen,—I have the lightest and briefest task which has fallen to any of the speakers because it is to convey your thanks to His Royal Highness for promoting this meeting and presiding over it which he has done with his characteristic urbanity and dignity. I have come here entirely as an auditor and a learner to-day and I am not competent to speak of the high subjects which have been treated in so interesting a fashion, but I express the views of all, whether they come as teachers or learners, in saying how pleased we are to see the Prince of Wales restored once more. The first act after his recovery from his illness is to be once more foremost in good works and taking part in this Association which we all hope will do so much to prevent a terrible disease.

Digitized by Google

Mr. WALTER LONG, M.P., seconded the resolution which was cordially carried.

The PRINCE of WALES, replying to the vote of thanks, said: I beg to tender my thanks to the speakers for the very kind way in which they have moved this vote of thanks to me for occupying the chair. I assure you it has been a great privilege to preside at so interesting and so important a gathering. When my friend Sir William Broadbent asked me to take the chair I gladly assented because I felt that notwithstanding my want of knowledge of this particular subject, and possibly of medical subjects generally, and feeling that a more competent person than myself should have occupied the chair, still in doing so I take the chair to prove to you the deep interest I take in this very important subject. We have all listened to the able and clear statement which has been made by Sir William Broadbent which has proved to you all the great importance of the National Association for the Prevention of Consumption which has been organised. We have all listened with interest to the able speakers who are thoroughly masters of the subject under discussion and I am glad to think that in Scotland and Ireland their attention has been called to this subject so deeply and that good work is being done. Lord Salisbury alluded to our being backward in this country in making such efforts as might prove advantageous for stamping out this fell disease. I am inclined to think so too. I believe in Germany, Sweden, Switzerland, and America they have gone ahead of us and we should follow their good example. The three points which Sir William Broadbent alluded to were, first, educating the public to prevent the spread of consumption from those already suffering. Now it is obvious to all that this is important and the way in which much can be done is to extinguish tubercle in cattle. I agree with Lord Salisbury that to try to pass a law which would force farmers to perform operations on their cattle would possibly be unpopular; but still if people would sometimes sacrifice their cattle which are suffering from tuberculosis they would do more by good example in stamping out this complaint. I mention the matter because I have been informed that Her Majesty the Queen gave authority that thirty-six of her dairy cows at her Home Farm which on being tested by tuberculin were found to be tuberculous were to be destroyed. In regard to sanatoria, I have just alluded to how this disease should be stamped out, but when it exists the great object is to cure it. No doubt these sanatoria, one of which I visited at Falkenstein, and which impressed me greatly, are very useful. Our climate has been against our having them before. In Germany and Sweden and Switzerland the climate lends itself to this mode of life more than we find here. Though, I think, on the whole our climate is the best in the world, unfortunately we do suffer from vicissitudes of temperature and dampness which everyone knows is bad for consumption. I was much struck at Falkenstein at the sanatorium under Dr. Dettweiler which is a sanatorium that everyone would wish to follow in England. I was told that in the village at Falkenstein there was no case known of consumption the arrangements were so good, and there was no means of the villagers becoming contaminated. I do not know that there is any more for me to say. I can only repeat that not only do I take the deepest interest in this important subject, but if anything lies in my power to further this great object I shall only be too proud to do it and to give my assistance to this Association. I thank you for listening to me and for the remarks about my health the improvement in which has given me the opportunity of standing before you to-day.

Before leaving the Prince took the opportunity of thanking the London partners of Messrs. Werner, Beit, and Co. for their gift of £20,000 to the new sanatorium.

FREEMASONRY.—A meeting of the Æsculapius Lodge, No. 2410, was held at the Café Royal, Regent-street, on Dec. 14th, the Master, Bro. Surgeon-Lieutenant-Colonel H. W. Kiallmark, G.J.D., presiding. Bros. Pakes and Eaton were admitted to the third degree. Mr. Ridley Herschell and Mr. J. C. Earls were initiated into freemasonry. Bro. Dutton gave notice that at the next meeting he would propose that the Masters of the Cavendish and Sancta Maria Lodges for the time being be elected honorary members of the Æsculapius Lodge. After the business of the lodge was concluded the members dined together, some distinguished visitors being present.

THE AMERICAN ARMY MEDICAL DEPARTMENT IN THE SPANISH-AMERICAN WAR AND THE REPORT OF THE SURGEON-GENERAL OF THE UNITED STATES ARMY.

THE investigation undertaken at the unanimous wish of the people of the United States for the purpose of inquiring into alleged mismanagement during the Spanish-American war and to endeavour to place the blame on the proper shoulders has now been proceeding for some weeks. A principal if not the chief charge brought against the authorities is that the medical attention given to wounded and sick soldiers was altogether inadequate and in many instances completely lacking; that some of the ships used for transporting invalid soldiers from Cuba were in a dirty and insanitary condition besides not being properly fitted for the purpose; and, lastly, that the health of the soldiers who remained in the country was menaced and often injured by the injudicious choice of camp sites and by the want of ordinary care in keeping these camps in a sanitary condition. The committee of investigation is still at its labours, so that until the final result of the inquiry is made public it is unfair to pass an opinion on the matter. In the meantime, however, the report of Surgeon-General Sternberg on the work of the American Medical Department during the war has been published. In this report General Sternberg freely admits that there were many defects in the organisation of the Army Medical Service, but claims that under the conditions existing at the time of the outbreak of war this inefficiency was unavoidable. Surgeon-General Sternberg says that the very small proportion of medical officers having experience of a military character impaired the efficiency of the department at the outset; that inadequate provision having been made for Hospital Corps men for the volunteer troops, in order to provide this corps with the necessary number of men recruiting officers were urged to secure suitable men and medical officers to effect the transfer of men from the line of the army; that 1700 female nurses were enrolled and employed at first at the general hospitals and later at the field division hospitals; and finally that ample supplies for six months were ordered immediately. With regard to the health of the troops Surgeon-General Sternberg says: "In my opinion the reduction of the age limit from twenty-one to eighteen years and the haste with which the volunteer regiments were organised and mustered into the service were responsible for much of the sickness which was reported in the early days of their camp life. ..... Soon after the newly raised levies were aggregated in large camps sickness began to increase progressively from causes that were so general in their operation that scarcely a regiment escaped from their harmful influence. These causes may largely be referred to ignorance on the part of officers of the principles of camp sanitation and of their duties and responsibilities as regards the welfare of the enlisted men in their commands. Medical officers, as a rule, were also without experience in the sanitation of camps and the prevention of disease among troops. The few who knew what should be done were insufficient to control the sanitary situation in the large aggregations of men hastily gathered together." Concerning the medical statistics of the war the report says: "My report presents tabulations compiled from monthly reports of sick and wounded received from May to September inclusive and representing a strength present of 167,168 men. These give full particulars of 1715 deaths, of which 640 were occasioned by typhoid fever, 97 by malarial fevers, and 393 by diarrhœa and dysentery. The death-rates for May and June, 46 and 70, were not in excess of those of the army in time of peace. In July the rate became somewhat higher than that of most well-cared-for cities, 2·15 for the month, or the equivalent of an annual rate of 25·80 per thousand living. In August it became excessive, 4·08 for the month, equal to an annual rate of 48·96 per thousand. In September the influence of the energetic measures taken in July and August to improve the health of the army becomes manifest in the falling of the death-rate to 2·45, or the equivalent of an annual rate of 29·40."

The lay papers in all parts of the United States, together

Digitized by Google

with some of the medical journals, have criticised adversely the management by the Army Medical Department during the war. Among the medical journals the *New York Medical Record* was foremost in raising a protest against some of the methods of conducting matters medical in the Cuban campaign and in an able and temperate article in its issue of Dec. 3rd commenting on Surgeon-General Sternberg's reports continues to discuss the question and says: "While the shortcomings charged against the medical department of the army are still fresh in the minds of the nation it is becoming and proper to view the statements set forth in that spirit of justice and impartiality which seeks only the truth and the lessons which it may be capable of teaching. Although the general impression created by the calm analysis of the situation is one scarcely favourable to the present organisation of the medical corps as to its capacity or resources, there is a general conviction that the best was done for the sick and wounded that was possible under the circumstances of conflicting authority, inadequate preparation, and the culpable want of forethought of the line officers." The article ends thus: "Our experience in the late war, dearly bought as it has been in much preventable sickness, suffering, and death, has offered us many striking object lessons in army organisation which will doubtless be of great service to us in the future. There has been demonstrated a pressing need of centralised power in the consistent distribution of those responsibilities which may make the army and all its different departments a grand and perfect machine. In every branch of the service there are too much antagonism of interest and too much shifting of blame from one to the other to make any break or starting-point in the convenient and bewildering round-robin system of common protection. So long as the present plan exists no change for the better need be expected. In regard to the transportation of food and medical supplies the quartermaster's department in its supreme and wide-reaching executive capacity decides absolutely all questions of emergency as to precedence and detail. Unfortunately the medical department is generally last of all considered and is made to wait its turn at the foot of the list. Ancient experiences in this line repeated themselves in the war with Spain with such disastrous results that an official investigation was made imperative. What the real outcome of the inquiry may be cannot be conjectured, but it is hoped that the great mass of testimony taken may ultimately eventuate in some formal recommendation for the reorganisation of our army supply system whereby the dreadful mistakes so familiar to all may be effectually prevented in the future."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6281 births and 3575 deaths were registered during the week ending Dec. 17th. The annual rate of mortality in these towns, which had been 19·1 and 17 8 per 1000 in the two preceding weeks, further declined last week to 16·6. In London the rate was 16·5 per 1000, while it averaged 16·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·9 in Derby, 11·7 in Croydon, 12 0 in Hull, and 12·4 in Burnley; the highest rates were 20·9 in Manchester, 21·5 in Swansea, 21·7 in Sunderland, and 21·9 in Nottingham. The 3575 deaths in these towns included 372 which were referred to the principal zymotic diseases, against 426 and 399 in the two preceding weeks; of these 103 resulted from diphtheria, 97 from measles, 60 from "fever" (principally enteric), 55 from whooping-cough, 33 from diarrhœa, and 24 from scarlet fever. No fatal case of any of these diseases occurred last week in Burnley; in the other towns they caused the lowest death-rates in Plymouth, Derby, and Wolverhampton, and the highest rates in Norwich, Swansea, Nottingham, and Bolton. The greatest mortality from measles occurred in Nottingham, Manchester, and Bolton; from scarlet fever in Swansea; from whooping-cough in Swansea, Cardiff, and Preston; and from "fever" in Swansea, Salford, and Sheffield. The 103 deaths from diphtheria included 40 in London, 10 in Swansea, 7 in West Ham, 7 in Liverpool, 7 in Leeds, 6 in Sheffield, and 4 in Birmingham. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Dec. 17th, was 3043, against 3162, 3142, and 3090 at the end of the three preceding weeks; 260 new cases were admitted during the week, against 234, 264, and 276 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 340 and 295 in the two preceding weeks, further declined last week to 283, and were 160 below the corrected average. The causes of 36, or 1·0 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Manchester, Bradford, Hull, and in fourteen other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·0 per 1000 in each of the two preceding weeks, declined to 19·4 during the week ending Dec. 17th, but exceeded by 2·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Perth and 13·1 in Paisley to 21·2 in Dundee and 22·2 in Aberdeen. The 584 deaths in these towns included 16 which were referred to whooping-cough, 12 to scarlet fever, 12 to diarrhœa, 10 to "fever," 8 to measles, and 6 to diphtheria. In all, 64 deaths resulted from these principal zymotic diseases, against 83 and 71 in the two preceding weeks. These 64 deaths were equal to an annual rate of 2·1 per 1000, which was 0·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 21 and 16 in the two preceding weeks, were again 16 last week, of which 9 occurred in Glasgow and 3 in Dundee. The 12 deaths referred to scarlet fever exceeded by 2 the number in the preceding week, and included 5 in Glasgow, 3 in Greenock, and 2 in Edinburgh. The deaths referred to different forms of "fever," which had been 10 and 11 in the two preceding weeks, were 10 last week, of which 6 occurred in Glasgow and 3 in Aberdeen. The 8 fatal cases of measles showed a further decline from recent weekly numbers, and included 5 in Glasgow. Of the 6 deaths from diphtheria 2 were recorded in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 147 and 163 in the two preceding weeks, declined again to 132 last week, and were slightly below the number in the corresponding period of last year. The causes of 26, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 31·6 and 25·4 per 1000 in the two preceding weeks, further declined to 25·2 during the week ending Dec. 17th. During the past four weeks the death-rate in the city has averaged 28·3 per 1000, the rate during the same period being 17·0 in London and 22·0 in Edinburgh. The 169 deaths registered in Dublin during the week under notice were within 1 of the number in the preceding week, and included 15 which were referred to the principal zymotic diseases, against numbers declining from 17 to 8 in the three preceding weeks; of these, 6 resulted from "fever," 5 from whooping-cough, 3 from diphtheria, 1 from scarlet fever, and not one either from small-pox, measles, or diarrhœa. These 15 deaths were equal to an annual rate of 2·2 per 1000, the zymotic death-rate during the same period being 1·6 both in London and in Edinburgh. The deaths referred to different forms of "fever," which had been 2 and 4 in the two preceding weeks, further rose to 6 last week. The fatal cases of whooping-cough, which had been 3 in each of the two preceding weeks, rose to 5 last week. The 3 deaths from diphtheria exceeded the number recorded in any recent week. The 169 deaths in Dublin last week included 29 of infants under one year of age and 48 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons exceeded the number recorded in the preceding week. Six inquest cases and 5 deaths from violence were registered; and 60, or more than a third, of the deaths occurred in public institutions. The causes of 12, or more than 7 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

FLEET-SURGEON DUDLEY retires on half pay and is succeeded at the Royal Naval Hospital, Netley, by Fleet-Surgeon Standish O'Grady.

The following appointments are notified:—Surgeons: A. H. L. Cox to the *Victory*, C. Bradley, to the *Cambridge*, B. G. Heather to the *Magnificent*, T. Austen to the *Vivid*, and S. Croneen to the *Victory*.

ROYAL ARMY MEDICAL CORPS.

Captain Rawnsley embarks for service in India shortly. Major Hart is appointed Acting Principal Medical Officer, North-Western District. Majors Forman and Birrell have embarked for duty in India. Majors Wright, Russell, Stoney, and Power, and Captain Browne are *en route* to India in the transport *Dunera*. Major James and Captains Thacker and Buist arrive home next week from India in the transport *Dilwara*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Brigade-Surgeon-Lieutenant-Colonel Frederick Augustus Smyth (Bengal) retires from the service, as does also Lieutenant-Colonel Walter Conry (Bengal). Surgeon-General W. A. Catherwood, A.M.S., to be Principal Medical Officer, Bengal Command, vice Surgeon-Major-General T. Walsh, A.M.S., retired. Captain R. H. Maddox to be Personal Assistant to the Principal Medical Officer, Bengal Command, *pro tem.*, vice Major G. B. French.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain W. B. Moir, having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers. Surgeon-Lieutenant David Livingston Hamilton, 4th Volunteer Battalion the Manchester Regiment, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Midlothian: Surgeon-Captain G. Mackay resigns his commission. 1st Worcestershire and Warwickshire: Arthur Charles Oldham to be Surgeon-Lieutenant. *Royal Engineers* (Volunteers): 1st Hampshire: Henry Fulton to be Surgeon-Lieutenant. *Rifle:* Galloway: The under-mentioned officer retires, with permission to retain his rank and to continue to wear the uniform of the corps on his retirement: Surgeon-Lieutenant-Colonel W. Lorraine. 1st Volunteer Battalion the Cheshire Regiment: Lieutenant Andrew Robertson Wilson resigns his commission and is appointed Surgeon-Lieutenant. 3rd Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant J. Abernethy resigns his commission. 1st Nottinghamshire (Robin Hood): Robert Henry Cordeux to be Surgeon-Lieutenant.

ABSCESS OF THE LIVER IN DUTCH INDIA.

During the biennium 1894–95 46 patients were admitted to the military hospital at Soerabaya in Java on account of hepatitis, the disease in no fewer than 25 instances being complicated with suppuration of the gland. In 2 of these 25 cases the presence of pus was not recognised until after death. In 5 the pus made its way spontaneously either through the lungs or by the bowels; 2 of these patients recovered and 3 died. 4 cases recovered after evacuation of the abscesses by simple puncture (in one of these cases injection of the sac was practised after the removal of the pus). In 5 cases the abscesses were incised without resection of ribs. One of these proved fatal. Finally, out of 9 cases in which incision was accompanied by resection there were 5 deaths. The total mortality, 11 out of 25, was consequently equal to 44 per cent., and the post-operative mortality, 6 out of 18, to 33 per cent. In the military hospital at Malang during the same period 12 cases of abscess of the liver were treated. Spontaneous evacuation occurred twice with 1 death. 1 case recovered after simple puncture and 2 after incision of gland without resection of ribs. Out of 7 cases of incision with resection 3 recovered, 2 died, and 2 were doing well at the close of 1895. The total mortality was equal to 25 per cent. and the post-operative mortality to 20 per cent. For the above notes we are indebted to the *Medical Journal of Dutch India*.[1]

VOLUNTEER AMBULANCE SCHOOL.

The prizes won by successful members of the above school were distributed by Lieutenant-General Sir George White, V.C., Quartermaster-General, on the evening of Wednesday, Dec. 14th, at St. Martin's Town Hall, Charing-cross. Brigade-Surgeon-Lieutenant-Colonel P. B. Giles, said that the Volunteer year 1897–98 had been a most successful one for the school. The classes had been well attended and the percentage of passes was very high. Sir George White, introduced by the president, Major Andrew Maclure, said that it gave him great pleasure to find himself associated with such an institution, as it showed that volunteers had not enrolled themselves for the defence of their country without due consideration of its rougher and sterner aspects. Prompt and efficient medical aid was essential for the alleviation of that suffering which must be part of a field of battle. He could bear testimony to that alleviation. A Bohemian entertainment was given during the evening and was thoroughly enjoyed by a very large audience.

THE ROYAL ARMY MEDICAL CORPS.

We may remind our readers that an examination for 24 commissions in this corps will be held in London on Feb. 3rd next and the following days. It is well known that the Royal Army Medical Corps has for some time been below its establishment and that as a consequence the home tour has been very brief as compared with that which medical officers have to put in on foreign service. This is very naturally productive of much discontent. We should have thought that with the view of overcoming this difficulty it would have required more than 24 candidates and it is quite possible that the recognised strength of the establishment requires to be augmented to meet the increasing demands upon it. Be this as it may, it is only right to say that the Government has conceded what the medical officers of the Army asked for and there is therefore no longer any reason on that score why young medical practitioners and students should not turn their attention to the Royal Army Medical Corps.

Captain Charles Christie Fleming, R.A.M.C., employed with the Egyptian Army, has been made a Companion of the Distinguished Service Order in recognition of his services during the recent operations in the Soudan.

"Audi alteram partem."

THE SOURCES OF PUERPERAL FEVER.

To the Editors of THE LANCET.

SIRS,—Permit me to offer a few observations upon the conclusions of Dr. Whitridge Williams cited in an annotation in THE LANCET of Nov. 26th: "We shall not go far wrong if we regard the vagina of a healthy woman as free from all such organisms as usually produce puerperal fever," and that "death from puerperal infection is always due to infection from without," and that it "is usually due to neglect of aseptic precautions by physician or nurse." This doctrine may entail a grave reproach upon the physician and may expose him to the charge of malpractice if not of manslaughter. Before accepting this absolute and dangerous doctrine it is well to analyse the grounds upon which it is constructed. In the first place it is fair to observe that Dr. Williams's clinical observations are limited to "40 cases of fever in the puerperium," occurring, it may be presumed, in a very limited field; secondly, that "the vaginal secretion of pregnant women does not contain the usual pyogenic cocci"; and thirdly, that as the vagina does not contain pyogenic cocci auto-infection with them is impossible." Thus Dr. Williams builds up his doctrine on the assumption that there can be no auto-infection without pyogenic cocci. This is simply begging the question. A fundamental fallacy in the pursuit of the problem of puerperal fever has been the search for one all-embracing cause. But the laws of biology are not so simple. We must be prepared to accept many facts and not hastily to reject any.

It is well at the outset to understand what is meant by the term "puerperal fever." Is it one definite constant fever? Or is it not more logical to use the term "fever in a puerpera"? This expression—I will not call it a definition—clears the ground for free unprejudiced observation and analysis. When we see a puerpera suffering fever, unbiassed by arbitrary doctrine, we study all the associated conditions.

Digitized by Google

In a proportion of cases undoubtedly we trace the action of a poison intruding from without. But there are certainly many cases in which the intrusion of a poison from without cannot be traced, and in which the essential causes spring in the patient's system. Fevers resulting from infection from without I originally distinguished by the term "heterogenetic" and those arising from processes inherent to the subject by the term "autogenetic." These terms have come into extensive use, but I have substituted for them "exogenetic" and "endogenetic." Nor are these quite satisfactory.

It is superfluous here to dwell upon the exogenetic forms of fever. It is enough to remember that many poisons, as zymotics, septic and others, account for a large proportion of cases. But do they account for all? When a woman is delivered there sets in at once a process of disintegration of superfluous tissue which has to be got rid of by disintegration, absorption, metabolism, and excretion. So long as the excretion of waste stuff keeps pace with its disintegration, absorption, and excretion the condition is physiological. But as soon as the physiological balance is disturbed the blood, becomes loaded with effete matters. Then any adequate disturbing factor may check the physiological disposal of the effete stuff, toxæmia ensues, and fever, endogenetic, sets in. The disturbing factors are many—chill, checking excretion by lungs, liver, kidneys, or skin; violent emotion or other form of nervous shock will often start fever. Evidence of the excretory and metabolic process in puerpery is proved by lactation, the *gravis odor puerperii*, and other phenomena. This *gravis odor* may be a source of toxæmia. This is seen in lying-in hospitals. Patients who go on breathing air tainted with their excretory emanations become easy prey to any disturbing influence. We may observe analogous conditions in menstruation, the analogue of gestation and puerpery. Who has not smelt the *gravis odor* of menstruation? Here there is no wound, unless we call the casting of the superficial cells of the uterine mucous membrane a wound. Yet there is absorption of effete matter which ought to be excreted. Arrest this process suddenly and there arises a form of toxæmia and fever analogous to the endogenetic puerperal fever. In some cases of retained menstrual fluid, absorption arises. To this condition I have applied the term "menosepsis."

The peculiar alteration of the blood induced by severe nervous and muscular exertion, like that which attends parturition, is illustrated in over-driven cattle, in animals hunted to death, in soldiers killed after a long fight. In these cases post-mortem rigidity comes quickly, is of short duration, and putrefaction soon begins. A woman who has undergone a severe labour presents similar phenomena. Thus we find in protracted labour a cause of endogenetic puerperal fever. I am, Sirs, yours faithfully,

Lingwood, Liss, Dec. 18th, 1898. ROBERT BARNES.

"DIPHTHERIA ANTITOXIN IN PRIVATE PRACTICE."

To the Editors of THE LANCET.

SIRS,—I have been much interested by reading in THE LANCET of Dec. 3rd and 10th the important papers on the above subject by writers of note, but I cannot help thinking that some of the deductions arrived at in the paper written by Mr. Bousfield are somewhat fallacious. Whilst advocating the very early use of antitoxin in suspicious cases he considers it to be a "diagnostic agent" as well as a curative one. To the former (which I have written in inverted commas) I must take exception. Two brothers, A and B, were admitted to the hospital here this year with typical scarlet fever rash all over the body and ulcerated throats. The throat of A was very like diphtheria on the left side and I gave two injections of 1500 B. units on successive days. The bacteriological report of the specimen sent on the day of the boy's admission was "No Klebs-Löffler," yet this boy's throat was quite clear in five days without any other treatment. B was treated with chlorate of potash, &c., but even after eight days there was very little difference in the appearance of his throat. To further test therefore the effect of antitoxin in bad scarlet fever throats would be somewhat interesting.

Mr. Bousfield later says: "Since the membrane clears off the throat within at most forty-eight hours it seems clear that there can be no further growth of virulent diphtheria bacilli and that a week probably represented the outside time during which it is necessary to isolate the patient." Surely this is a very dangerous dogma. I grant that as a rule the membrane clears off as stated, but I have seen it remain for more than five days. Is absence of membrane a proof of absence of virulence in the patient? For we know already that diphtheria may exist without the formation of membrane. There is absolutely no doubt in my mind that a large majority of patients are infective even in the absence of membrane for a much longer period than a week.

Diphtheritic patients in this small conjoint hospital containing 8 scarlet fever and 8 diphtheria beds are not discharged so long as the bacillus exists and I find that during the past four years patients have remained under treatment for not less than six weeks at any time, although for the past eighteen months formalin has been vapourised in the diphtheria wards every other day and the throats of some of the patients have been painted with formalin solution. I have now used the antitoxin over 100 times (34 times last year) and am therefore able to contribute my mite of observation on this important subject.

I am, Sirs, yours faithfully,

FRANK ARGLES,
Medical Officer of Health and Medical Officer to the Conjoint Hospital, Wanstead.

Wanstead, N.E., Dec. 16th, 1898.

To the Editors of THE LANCET.

SIRS,—In connexion with the admirable article by Mr. Bousfield in THE LANCET of Dec. 10th my experience with antitoxin in a country practice may offer some points of interest. From April 3rd, 1895, to Feb. 6th, 1896, I notified 41 cases of diphtheria, all of which recovered. Of these, 39 were treated with antitoxin. In 2 cases tracheotomy had to be resorted to as well and in both recovery was uninterrupted and rapid. All of the cases occurred in children under sixteen years of age except 3, 1 in a man aged thirty years, 1 in a woman aged thirty years, and the other in a woman over seventy years of age. Only in 5 instances did 2 cases occur in the same house, 4 times simultaneously and once the second case appeared three weeks after the first. In the first 4 instances the patients were all girls and the boys in the family escaped; in the fifth the mother was the first case and her two-year-old son was the second. In one instance 3 cases occurred in one house, the first on August 7th, the second on Sept. 12th, and the third on Nov. 21st; all were girls. Amongst the 41 cases 30 were females. Two cases were followed by paralysis. In every case the skin was washed first with soap and water and then with a lotion of carbolic acid and the syringe and all its parts were sterilised by boiling. In a few instances a small abscess nevertheless formed at the seat of injection and a few injections were followed by urticaria, although it struck me at the time as curious that when I injected two patients with the same serum one would get urticaria and the other would not. The injections were always made into the subcutaneous tissue of the abdomen and in no case was it found necessary to administer more than one injection. The membrane had in most cases disappeared within forty-eight hours and the employment of the remedy has been eminently satisfactory. The injection consisted usually of 10 cubic centimetres of serum supplied by the British Institute of Preventive Medicine. Although situated over 200 miles from London, by sending a telegram before 3 o'clock in the afternoon I was always sure of a supply before 8 o'clock the next morning. In one case, one in which tracheotomy was resorted to on account of the fulminating rapidity of the symptoms, it was not deemed advisable to wait until the following morning and I was fortunately able to procure some serum supplied by Messrs. Burroughs, Wellcome, and Co. from a local agent. Still, in most cases I could be satisfactorily supplied from London.

There is one other point which I am desirous of mentioning, not necessarily as an example to be followed. The last of the above-mentioned 41 cases occurred on Feb. 6th, 1896. From that time no other case occurred in my practice until May 21st of the following year when a part of the supply received from the last case was used without any ill effect, neither urticaria nor abscess nor any other untoward symptom resulting, and the same may be said of the remainder of the same supply which was used for my next case on April 21st, 1898, twenty-six months after it was received. With regard to the expense of the treatment I have looked at the matter

Digitized by Google

from many points of view and I cannot see that it is any more costly than any other form of treatment. It is certainly one which involves little trouble and anxiety and much satisfaction to both patient and medical man. To summarise, this treatment is one which may be easily and inexpensively carried out even in remote places with very satisfactory results.—I am, Sirs, yours faithfully,

JAMES A. SAMUEL, M.D. Leipzig, L.S.A.

Torpoint, Devonport, Dec. 20th, 1898.

To the Editors of THE LANCET.

SIRS,—My experience in the treatment of diphtheria with antitoxin may perhaps interest some of your readers. Mine is an entirely country practice and upon my coming here I learned that diphtheria had been prevalent for something like eighteen months with a high percentage of deaths. My first case occurred on Dec. 8th, 1897, and from that date till Oct. 23rd, 1898, I had 33 cases, varying from the mildest to some very severe ones. In every case antitoxin (supplied by Messrs. Burroughs and Wellcome) was injected at once in a full dose, repeated two days after if necessary, and in the very worst cases injected a third time. In most of the cases and in all doubtful ones a swab was taken and a bacterial examination was made to verify the diagnosis. I have had no deaths. In all but exceptional cases the patient has been convalescent—indeed, I might say well—within the week. Only one or two showed signs of paralysis, and this but slight and evanescent. Urticariæ appeared in about five cases and inflammation or other untoward symptoms in none. I invariably injected the antitoxin into the tissues of the back below the scapula. In June last seeing that the spread of the disease continued even after isolation of the patient for six weeks, the rural district council decided that every patient should be pronounced free from the Löffler bacillus after bacterial examination before being allowed out of quarantine. This showed strange results. In some instances patients were free at the end of three weeks, others not till the lapse of two months, the apparently mildest cases being often the longest to throw off the bacillus. From the institution of this procedure the disease gradually died, no other case having occurred since Oct. 23rd last. This experience leads me to the conclusion that antitoxin used at once in full doses, repeated, if necessary, a second or even a third time, is the only treatment which need be employed to bring about success; also that so long as the diphtheria bacillus is present in the discharges about the throat, as shown by the result of a bacterial examination of a swab taken therefrom, so long is the patient an infectious person and to be isolated.

I am, Sirs, yours faithfully,

W. J. NICHOLLS, M.R.C.S. Eng., L.R.C.P. Edin.,
Medical Officer and Public Vaccinator, No. 4 District, Chipping Norton Union.

Milton-under-Wychwood, Oxon., Dec. 19th, 1898.

To the Editors of THE LANCET.

SIRS,—In connexion with the above subject may I add my experience, though limited, as a general practitioner? Within the past year I have had 9 cases of diphtheria with a mortality of 1, or about 11 per cent., the fatal case being a child whom I did not see until the fourth day of illness and who was practically in a moribund condition before injection. I am in entire accord with Mr. Bousfield as to the great value of an early injection, and may mention that I also use the serum supplied by Burroughs, Wellcome, and Co., some of that I have used having been kept for over two months. The only complication I have seen following its use has been an erythematous scarlatinoid rash which appeared in one case some days after the temperature had fallen to normal and which spread from the site of injection slowly over the whole surface of the body, being unaccompanied by any constitutional disturbance or rise of temperature. Two of the cases had severe laryngeal complications, in one of which I had arranged to perform tracheotomy, but after an injection of 1500 units, the quantity I usually inject, in a few hours the dyspnœa had abated so much as to render operation unnecessary. I first saw this case on the fourth day of illness. In diphtheria affecting the larynx primarily (membranous croup) I have injected antitoxin in one case which I first saw three days after the commencement of the illness and in which there was urgent dyspnœa, with the most gratifying result. As regards the site of injection I prefer the lumbar region of the back close to the spine, as by placing the child flat on its stomach its movements are easily controlled and, unlike an injection into the abdominal parietes, there is no risk of a sudden struggle causing the needle to perforate the abdominal wall.

I am, Sirs, yours faithfully,

H. C. BEASLEY, L.R.C.P., L.R.C.S. Irel.

Ashford, Middlesex, Dec. 19th, 1898.

To the Editors of THE LANCET.

SIRS,—Some of your correspondents seem astonished that diphtheria antitoxic serum is not universally used in private practice. I think I can enlighten them a little on this point. I, like one of your correspondents, have acted as assistant medical officer to one of the Metropolitan Asylums Board hospitals and there I was so convinced of the good results obtainable by the use of serum in cases of diphtheria that when recently I gave up hospital work for private practice I determined to adopt its use. I therefore purchased at a cost of a guinea an antitoxin syringe similar to that used at the hospital. But on looking up the price of the antitoxic serum in Parke, Davis, and Co.'s price list I found that 16,000 units (at 17*s.* 6*d.* per 2000 units) would cost £6 18*s.* I may mention that at the Metropolitan Asylums Board hospital at which I worked 8000-16,000 units was no uncommon dosage for a single case during the first forty-eight hours and I have seen 24,000 units administered. Then, too, to be of the greatest benefit the antitoxic serum must be immediately obtainable and that in many places means that it must be stocked by the practitioner himself. But to stock a perishable article like the serum means an additional expense.

Perhaps, Sirs, some of your readers will kindly advise the private practitioners who work in those districts in which sanitary authorities do not provide serum and in which, as is sometimes the case, practices include patients who have only small or moderate incomes, as to the ways and means of carrying out this admirable treatment. In particular, who should pay for the serum? Apart from the question of the cost of the serum the operation itself of injection, though very simple, has undoubtedly several deterrent characteristics, which make it more difficult to apply in private than in hospital practice—(*a*) it is painful to the patient; (*b*) the struggles of the child, if such the patient be, alarm the friends and relatives; (*c*) the injection tumour, though transient, is pretty obvious to the naked eye; and (*d*) time and trouble must be spent in antiseptic precautions. The least failure in these precautions means an abscess, and an antitoxin abscess is particularly prone to give rise to sloughing of the surrounding tissues.

I am, Sirs, yours faithfully,

Bournemouth, W., Dec. 17th, 1898. H. E. G.

"VITALITY."

To the Editors of THE LANCET.

SIRS,—You as well as your readers will, I am sure, agree with me in thinking that for the discussion of this question of "Vitality" a liberal amount of your space has been assigned. As I shall ask you next year to allow me to bring before my brother practitioners some further communications with reference to the bearing of "Vitality" upon the nature of morbid changes and upon the practice of medicine, I am anxious that your readers should not be tired of my work and therefore hope that for the present you will decree the "closure." Bear with me, however, while I draw attention to the letter on "Vitality" in THE LANCET of Dec. 3rd, page 1506, the writer of which considerately provides me with a more than adequate reason for declining further discussion for the present. He has appalled me by comparing my silent, peaceful, intangible "vitality" with horrid subterranean fires and dreadful violence, the last remains of antevital phenomena persistent during millions of æons—to us inconceivable, unknowable, and unthinkable. "In the growth (!) of Mount Vesuvius and that of an oak tree," he says, "I see a great similarity." Well,—considering that my spirits have risen rather high in consequence of the favour with which my views on "vitality" have been received by your readers I may be pardoned if, finding it rather difficult to be serious, and at this festive season, I call attention to a most curious and comical "similarity" between Vesuvius and "vitality" which are undoubtedly

Digitized by Google

alike—in the number of their letters and in the number of their syllables, and do they not both begin with a V?

In conclusion let me propose that with due consideration and respect we consign to unfathomable volcanic depths our poor old "cell" with its walls and its non-living "contents," its supposed mechanical contrivances, its physical properties, and its dead and dying protoplasm, and let us look forward in hopeful confidence to the coming century and the gradual rise of living bioplasm, that lives and moves and forms and dies, and to the time not far off when the human mind shall be freed from its artificial fetters long imposed; and in accord with reason, shall demand its vital supremacy and acknowledge its transcendant position in the life world, which in times of comparative darkness as regards *natural knowledge* was accorded to it by tradition, contemplation, and thought—a position which by the advance of new knowledge and research will become for ever certain and secure. Let the human mind accept its great responsibilities and no longer bow to the reckless efforts to intimidate it and perplex its judgment with wordy sophisms forged to force it to believe that man is but one of the innumerable forms derived from the overwhelming vastness of lifeless matter, of which he sees around him and can study and know but an infinitesimal portion—man said to be one with the mechanisms he designs and makes—man asserted to be but one of the infinite powerless helpless outcomes of the material universe and passive immutable blind law!

I am, Sirs, yours faithfully,

Dec. 3rd, 1898. LIONEL S. BEALE.

*** This correspondence must now cease.—ED. L.

"A CASE OF DEATH FROM DIABETES MELLITUS IN WHICH THAT DISEASE GAVE NO PREMONITORY SYMPTOMS."

To the Editors of THE LANCET.

SIRS,—The following case, bearing a close resemblance to the one recorded by Dr. T. Wilson Parry in THE LANCET of Nov. 26th, 1898, came recently under my notice. The patient, a delicate-looking boy, aged eight years, was admitted to the Nottingham City Isolation Hospital on Sept. 3rd, 1898, suffering from a mild attack of scarlet fever. On Oct. 5th the patient who up to that time had progressed very favourably complained of headache and nausea. His urine on examination showed a specific gravity of 1025 and a faint trace of albumin. During the next two days the patient expressed himself as feeling quite well, though the slight albuminuria still remained. At 2 A.M. on Oct. 8th the patient woke suddenly from a sound sleep and commenced to scream with acute abdominal pain. As he was very constipated olive oil and simple enemata were given and a small, hard, dry motion was passed. The patient seemed much exhausted after this action of the bowels and aromatic spirit of ammonia was given as a restorative. Shortly afterwards the pain in the abdomen was relieved and the patient went quietly to sleep. At 7.30 A.M. he woke and passed a large motion of the same character as before. This was immediately followed by a sudden general collapse. At 8 A.M. the patient's condition was as follows: he was lying on his back semi-conscious; he could be roused when spoken to sharply but his answers were unintelligible; his face was pinched and drawn and there was much cyanosis of his lips and ears; his eyes were wide open, the pupils were dilated equally and reacted very slightly to light; his pulse could scarcely be felt at the wrist and his extremities were very cold; his heart sounds were weak—140 per minute; there were no murmurs; his respirations were slow, deep, and sighing, but nothing abnormal could be detected by examination of the chest. Examination of the urine gave the following result: the colour was pale, reaction was acid, the specific gravity was 1040, with a trace of albumin and a very large quantity of sugar. The coma gradually deepened and the patient died at 1 P.M. on Oct. 9th, thirty-five hours after the onset of the first symptom.

The chief interest in this case, as in the one recorded by Dr. Parry, lies in the sudden onset of fatal symptoms. The boy's parents stated that previously to the attack of scarlet fever he had always been a very healthy child and that he had certainly not had any of the usual symptoms of diabetes. For five weeks immediately preceding his death the patient was under close observation in this hospital and I am convinced that during this period and up to Oct. 8th his symptoms differed in no way from those of an ordinary healthy child convalescing from a mild attack of scarlet fever. The patient's urine had never to my knowledge been tested for sugar previously to the morning of Oct. 8th; the specific gravity had, however, been taken on several occasions and had never exceeded 1025.

I am, Sirs, yours faithfully,

T. O'NEILL ROE, M.B. Lond.,

Resident Medical Officer, Nottingham City Isolation Hospital.

THE GENERAL MEDICAL COUNCIL AND PRELIMINARY EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—I am instructed to send you the following table which was drawn up in this office from the returns supplied to the Medical Council by the various examining boards, including those for the Navy, Army, and Indian Medical Services, and submitted to the Education Committee when preparing the report quoted in Mr. Eve's letter to your journal of Dec. 17th. By an oversight in drafting the returns were described in the first lines of the paragraph quoted as if they came from the examining boards for the medical services only. These lines should read as follows: "During the years 1892–1898 returns have been made to the Council on behalf of the examining boards, including those for the Navy, Army, and Indian Medical Services, regarding those candidates who showed deficiency in general education." The necessary correction will be made in the report before it is issued to the public.

It will be observed that the summary of the statistics given in the remainder of the paragraph, and the conclusions drawn therefrom in the following paragraph of the report are in accordance with the figures in the table submitted to the Education Committee.

I am, Sirs, yours faithfully,

H. E. ALLEN,

Dec. 21st, 1898. Registrar of the General Medical Council.

Table showing the Numbers of Candidates reported as having been Deficient in General Education with the Preliminary Examinations passed by them during the Years 1892–1898.

* Examinations not now on the Council's list.

The original letter from the War Office calling attention to deficiencies in preliminary education appears in the Executive Committee's minutes for February, 1891. In 1893 seven persons were reported by the India Office (particulars not given). Also in 1893 one candidate, whose name could not be traced in the Students' Register, was reported by the

Digitized by Google

Conjoint Board of the Colleges of Physicians and Surgeons of Ireland. In 1896 one Army candidate, name not given, was reported for bad spelling. In 1897 one Army candidate was reported for bad spelling.

INFANTILE INSUSCEPTIBILITY TO VACCINATION.

To the Editors of THE LANCET.

SIRS,—It may be assumed to be generally accepted that there are several different causes which lead to the declaration that an infant is "insusceptible" to vaccination; well-known statistics such as those of Dr. Cory seem to show that vaccination performed thrice unsuccessfully by no means implies an actual insusceptibility to vaccinia and no doubt in a large majority of cases returned as "insusceptible" the vaccinator has been at fault either by scratching too minute an area of skin or by using inactive lymph, or, as has often been found, the mothers have prevented the success of the operation by purposely washing or otherwise interfering with the "places" immediately the vaccination has been completed. It will probably be agreed, however, that if such causes of failure are set aside there is a small residuum of cases truly insusceptible in the sense that vaccination of infants properly performed with efficient lymph on three occasions with intervals of a few weeks or months between them has failed altogether; and most vaccinators would recognise a degree of partial insusceptibility where out of several insertions of efficient vaccine over a considerable area made on each of two or more occasions at most a single small vesicle has resulted.

The purpose of my letter is to inquire of those who have had large experience of vaccination whether any information can be furnished of the relation, if any, between such truly insusceptible or partially insusceptible infants and the condition as to vaccination or variolation of the parents—particularly of the mothers. In the case of an infant born to a mother actually suffering from small-pox there are recorded instances in which the infant, vaccinated on several occasions with efficient lymph and remaining exposed to variola, has developed neither vaccinia nor variola. This appears to be the extreme case of true insusceptibility dependent on the maternal condition. Are there known comparable instances in which an infant has been born to a mother actually suffering from vaccinia and has proved insusceptible to vaccinations properly performed with efficient lymph? And, going further back, what has been the condition as to insusceptibility or partial insusceptibility of infants born to mothers who have suffered from variola or vaccinia before but not long antecedent to parturition? And, again, how long after birth does this insusceptibility last?

Beyond two cases recently under my observation of infants whose mothers had been successfully revaccinated shortly before commencement of pregnancy and who, after several vaccinations with lymph perfectly efficient and active when used in other cases both before and after these failures, presented in one case no reaction and in the other a single small vesicle on the second time of vaccinating, I am unable to contribute any facts upon the subject. But the matter has considerable interest and in Gloucester, Middlesbrough, and other places where no doubt there has lately been a considerable number of mothers vaccinated during pregnancy or having small-pox during or immediately antecedent to pregnancy there may have been several opportunities of observing what, if any, has been the degree of insusceptibility of their infants to vaccination.

I am, Sirs, your faithfully,

Chiswick-lane, W., Dec. 9th, 1898. G. P. SHUTER.

"THE 'OPEN-AIR' TREATMENT OF TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—When my letter on the "open-air" treatment of tuberculosis was inserted in your issue of Nov. 26th, that letter was written in London. This is dated from Arosa, at a height of over 6000 ft. in Switzerland. My letter has called forth a few remarks, one or two of which I should like to notice. I think Dr. Lionel Beale exactly hits it off when he says that life to be spent "in the contemplated sheds in many parts of England in such weather as we have lately enjoyed, would not be happy," and he might have added anything but beneficial. Then "M.O.H." proposes to erect at a cost of some £200 a heated greenhouse or glasshouse. One point seems to be entirely omitted and that is, as I before tried to emphasise, the essentials of these Alpine resorts—viz., intense *dryness* of the air, absence of wind, an intense *cold* dryness, brilliant hot sunshine, and lastly, the automatic expansion constantly going on of the lung under the atmospheric conditions such as cause the barometer to stand at from 24 in. to 23 in., and I still maintain that none of these conditions are in any way present or can be produced in England at any time of the year. Either the necessity for treatment under these conditions is a complete error or the method of building sanatoria in England is a mistake. Certainly the methods or theories in the treatment in England or in the high Alps in no way resemble each other. The conditions are, and must be, entirely different. I write as regards the *cure*—the permanent cure in many cases—of pulmonary tuberculosis, and I do really believe that the establishment in England of such sanatoria, though leading to possible improvement at the time owing to the greatly improved hygienic conditions and surroundings, will never in the same or even in more than a very minor degree lead to the arrest and cure of pulmonary tuberculosis.

I would add that the suggested cost of the glass erection suggested by "M.O.H." would more than pay for two seasons in the high Alps and he seems also to miss one of the chief points, and that is that the air in his "house" would be of necessity breathed and rebreathed. It is like applying a dirty dressing to a wound and it is only by being in the absolutely open air—not in rooms with even the windows open—that the same air is never breathed twice over The healthy lung may not actually suffer from inhaling the air over more than once—though it can certainly do it no good—but to the diseased lung the air breathed should be absolutely pure and this can only be obtained out of doors and not inside any building. I would finish by adding that Dr. Lionel Beale's description of the weather—four days of damp fog and wet and wind—more than fully confirms what I say about the impracticability of really carrying out the true "open-air" treatment of tuberculosis in England. I think I may say that unless it has been seen in its entirety as carried out here and in other high health resorts it is impossible to appreciate one-tenth of its benefits or the advantages to be derived from it or the actual methods employed. I am, Sirs, yours faithfully,

Arosa, Dec. 14th, 1898. A. G. P. GIPPS.

"COPYRIGHT IN PRESCRIPTIONS."

To the Editors of THE LANCET.

SIRS,—You were good enough to publish a letter f om me on the above subject some time ago[1] in which I advocated a scheme which would limit the use of prescriptions to the purposes for which they were intended, by granting copyright in them to their authors. By this means it would be easy to prevent a prescription written for a particular person at a particular time and in particular circumstances from abuse by being made up over and over again for an indefinite time and used at times and in manners and perhaps even by other persons which were never contemplated by the physician who was the author of the prescription. It is so clear to my mind that the author of a prescription should have control to such an extent of the way that it is applied that I feel sure that such an arrangement as I suggest must be brought about sooner or later, both as a matter of bare justice to medical men and also as conducive to the public welfare. A case that strongly enforces the desirability of such a scheme being carried out has lately come to my knowledge and is as follows:—

An inquest was held on Dec. 14th by Mr. Troutbeck, the coroner for Westminster, on the body of a lady, aged about fifty years. The jury returned a verdict of "Accidental death from an overdose of chloral hydrate." The following facts were given in evidence. The deceased had bought on Dec. 9th a 12 oz. bottle of a solution (syrup?) of chloral, containing 80 grains to the ounce, at one of the so-called coöperative stores. This bottle was obtained by means of a prescription that had been written for the deceased's husband who had died five years previously. His widow (the subject of the present inquest) had had it made up frequently

[1] THE LANCET, July 16th, 1898.

Digitized by Google

since. The manager of the drug department of the said stores stated that it was a common thing to make up prescriptions of long standing and that he had even made up a prescription as ancient as twenty-seven years! How often might not the Pharmacopœia have been altered in this time?

I think that the above example bears out what I formerly said and speaks strongly in favour of my views, and I would ask for opinions as to the best course to pursue. Would it not be the simplest to do as I suggest and bring the subject before the Copyright Commission (which I understand is to resume its sittings), so that the requisite provision may be embodied in the next Copyright Act?

I am, Sirs, your faithfully,

F. LUCAS BENHAM, M.D., M.R.C.P. Lond.

Elizabeth-street, S.W., Dec. 17th, 1898.

"REGINA v. WALLACE."

To the Editors of THE LANCET.

SIRS,—I thank you for the able leading article in THE LANCET of Dec. 17th on my case and also for the expressions of sympathy therein. There are one or two points in the case of interest to the profession generally apart from the fact that any medical man is liable to be charged similarly.

When I saw the girl first she was menstruating. She had headache, sickness, pains in the back, and a history of irregular menstruation. I also learned that she had worn a Hodge's pessary for a displacement. She menstruated again in March which fact was denied by the Crown though entered in my day-book along with the mixture she got for the pain. It was also denied that she had been irregular, though Dr. Daly of Eastbourne stated that he was told the same thing, only when he inserted the Hodge, having previously examined her, he could not say whether she had a hymen or not as he did not look for one. She missed April, having gone to Brighton and Reigate at her usual time of menstruating. When she came home on April 30th I saw her and prescribed iron. Off and on till May 13th she had sickness, pains in the back, and headache, all of which symptoms she had when she was menstruating in February. On May 13th she was very ill, all her symptoms were more pronounced, and she fainted; the headache was intense. This was the time she ought to have come on. I ordered hot fomentations round the pelvis. She was better in the evening. I reinserted the ring pessary on May 18th. On May 20th and 21st she had a "show." On May 25th I saw her. She had been delirious for two nights, had a temperature of 101·5°, a rapid pulse, and a tongue in keeping with these phenomena. That was the condition previously to the use of the sound as a repositor and a mechanical stimulant. The enlargement of the womb was very slight and it was fairly moveable and seemed to be of normal depth when I used the sound.

Because the girl had a miscarriage and I, like an honest fool, told the mother that the use of the sound had no doubt caused the miscarriage, I was arrested on a sworn statement, which was afterwards said to be false by the woman who swore it and denied also by the girl herself, who was alleged to have said I assaulted her when she was in a state of semi-collapse consequent on the pain caused by the removal of a 2 in. rubber pessary. Yet this was quite sufficient for the Crown to bolster up a case against me and with the help of a detective inspector who *swore* that he had examined my books and that there were no entries after March 12th, and yet on my visiting book which was on me when arrested every visit down to May 31st was in it and not a date was disputed when they were produced in court. I say with all this I was kept in Holloway Gaol eight weeks and finally allowed out on bail of three sureties of £500 *each* and myself in £1000, and after a lapse of six months tried and acquitted before Mr. Justice Hawkins (who when he had summed up left the Crown not a leg to stand on.

I am, Sirs, yours faithfully,

Beckenham, Kent, Dec. 19th, 1898. DAVID WALLACE.

CLEANSING THE LESSER PERITONEAL CAVITY.

To the Editors of THE LANCET.

SIRS,—In a clinical note in THE LANCET of Dec. 17th, 1898, under the heading of "Perforated Gastric Ulcer" Mr. Verrall has somewhat confused statements of mine contained in a paper which I read before the Brighton and Sussex Medico-Chirurgical Society last Nov. 3rd and since forwarded for publication. I gave prominence to the cleansing of the lesser peritoneal cavity and advised that the great omentum should always be opened in operation for perforated gastric ulcer. 1. To ascertain the condition of the posterior wall of the stomach. 2. To flush by introducing the nozzle of the irrigator the lesser cavity of the peritoneum which was sometimes the site of abscess in perforated ulcer even of the anterior wall, produced either (*a*) by the passage of gastric contents from the greater cavity to the lesser at the time of perforation or (*b*) by the gastric contents forced through the foramen of Winslow by the irrigating fluid at the time of operation. As I nevertheless advocated irrigation in preference to sponging I urged that the lesser cavity should be flushed not less thoroughly than the greater.

I directed the attention of members present to this suggestion, stating at the time that so far as I was aware it was a new one and that the condition of the lesser cavity had hitherto been neglected. Mr. Verrall remarked at the meeting that this was a new point and said that he thought it strange that it had been hitherto overlooked.

Although I find my recollection confirmed by that of others present at the meeting, proof of which I have enclosed privately, I should not have troubled you with this had I not felt that the good faith of the statement contained in my paper seems to be impugned by my colleague in his communication to THE LANCET last week.

I am, Sirs, yours faithfully,

Brighton, Dec. 17th. WILLOUGHBY FURNER.

*** We hope to publish Mr. Furner's paper next week.—ED. L.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

To the Editors of THE LANCET.

SIRS,—Will you oblige me by inserting the enclosed resolution which was passed on the occasion of the final annual general meeting of the London Post-Graduate Course?

That this meeting, having learnt with pleasure that another scheme for post-graduate work has been organised which will have the advantage of a central college and that most of those who have taken an interest in the London Post-Graduate Course are now concerned in promoting the new one, thinks it desirable that the London Post-Graduate Course should now terminate its labours.

Thus, after nine years of useful work this organisation gives way to the Medical Graduates' College and Polyclinic, which it is hoped will be largely instrumental in making London the greatest centre in the Empire for post-graduate study.—I am, Sirs, yours faithfully,

FLETCHER LITTLE, M.B. CANTAB.,
Hon. Sec. Medical Graduates' College and Polyclinic.

Chenies-street, W.C., Dec. 20th, 1898.

THE SEAMEN'S HOSPITAL SOCIETY AND ITS VISITING STAFF.

To the Editors of THE LANCET.

SIRS,—The "honourable apology" of the committee of the Seamen's Hospital Society is obviously insufficient and is followed by a confused attempt at explanation and extenuation which makes it practically no apology at all. Such as it is it has not reached the visiting staff in any shape or form except as a publication in the *British Medical Journal*, and it has been published in that paper only.

The committee state in the *British Medical Journal* that they do not contemplate the transfer of all tropical cases to the Branch Hospital. At least four times previously they have refused this information to the visiting staff of the *Dreadnought*. There are other matters at issue between the committee and us than the premature publication of Sir Henry Burdett's letter and the unauthorised statements contained therein. As some of the visiting staff of the *Dreadnought* were intended to be teachers in the proposed school it was obviously improper and open to misconstruction for the committee to be in consultation with the physician of the Branch Hospital without the knowledge of his assumed future fellow medical teachers of the *Dreadnought*, both of them much senior to him in the

Digitized by Google

service of the society. Even the statement of the committee that they have been in full and constant consultation with the visiting staff of the Branch Hospital cannot be allowed to pass.

The ophthalmic surgeon, who probably would have told us of what was going on, was like ourselves excluded from all information. His name was lately published in the list of the advisory committee without his consent, and it has now by his request been removed from it.

The committee quote an extract from Mr. Chamberlain's correspondence with them. It would be more satisfactory to have it *in extenso*. Are we to understand that the offer of public money came from the Colonial Office solely to increase the accommodation of the hospital to which the medical adviser to the Colonial Office is attached, that the committee deliberately kept their visiting officers of the *Dreadnought* in ignorance of their scheme until it had been decided to accept this offer, and to become responsible for the expenditure of this public money? If so, was this done with only one possible teacher of tropical medicine then at their disposal—the medical adviser to the Colonial Office himself?

The committee in their memorandum have referred to the assumption by this gentleman of the title of physician to the Seamen's Hospital, Greenwich (235 beds), when he was physician to the Branch Seamen's Hospital, Victoria and Albert Docks (18 beds), and say that we objected to his being so described. Dr. Manson really so described himself in Kelly's "London Medical Directory," 1895, Churchill's "Medical Directory," 1896, in the list of contributors to Davidson's "Hygiene and Diseases of Warm Climates," and in the *British Medical Journal*.

There is abundant evidence in the minute-book of the Seamen's Hospital Society and elsewhere to show that he was elected a physician to the Branch Seamen's Hospital at the Victoria and Albert Docks on the same day that Mr. Gunn was elected ophthalmic surgeon to the Seamen's Hospital Society. To this mistaken action of Dr. Manson's we took exception and for it he apologised. The matter has not hitherto in this controversy been publicly mentioned by us, although it might have ultimately become necessary, as we understand that this was the reason the committee deliberately refused to let us know of the proposed school.

Because the physician to the Branch Seamen's Hospital, Victoria and Albert Docks, was asked in 1896 why he described himself as physician to the Seamen's Hospital, Greenwich, the visiting staff of the latter are to have no voice in matters closely concerning them in 1898. Such has been the judgment of a committee that Sir William Broadbent has written "is unworthy of confidence." Resenting this criticism, they say they do not gather that the visiting staff have viewed their invitation as an insult or would join in Sir William Broadbent's protest. The visiting staff most cordially join in this protest against the treatment they have received and against the omission of parts of Sir Henry Burdett's letter. They regard the latter proceeding as unfair and misleading.

As the explanatory memoranda of the committee were not sent to any except a carefully selected *clientèle* from which we were excluded, it more than ever behoved the committee to omit nothing in the letter bearing on the present attitude of the visiting staff of the *Dreadnought*.

We are, Sirs, yours faithfully,

JOHN CURNOW, M.D., F.R.C.P.
JOHN ANDERSON, M.D., F.R.C.P.
G. R. TURNER, F.R.C.S.

Dec. 20th, 1898.

ACTION BY THE PHARMACEUTICAL SOCIETY.—At the Stonehouse County Court on Dec. 12th the Pharmaceutical Society brought an action to recover from Louis Fowler of Devonport a penalty of £5 for each of three infringements of the Pharmacy Act of 1868—viz., keeping "open shop" for retailing poisons and with using the designation of "chemist." The defendant admitted that he was not a pharmaceutical chemist although he had a qualified pharmaceutical chemist for his partner. Evidence showed that the defendant had used a label with an assumed name ("Livesay") and "dispensing chemist" written upon it and had also supplied two persons with oxalic acid and chlorodyne respectively. Judgment was given for the plaintiffs and the defendant was ordered to pay two penalties of £5 each for keeping "open shop," but the court did not think that he had rendered himself liable to a penalty for exhibiting the designation of "chemist."

THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 1668.)

To cope with the recrudescence of typhoid fever measures have been adopted which were not in force last year. As soon as a case is notified an inspector visits the house and fills up a form stating the condition of the drains, &c. If the house has a privy the inspector dissolves a tablet of corrosive sublimate in a pail of water and pours the water into the privy. He then leaves a pail, the ordinary metallic slop-pail with lid, for the use of the patient. At the bottom of the pail there is some sawdust mixed with carbolic acid. Instructions are given that all excreta from the patient must be kept in this pail and not thrown into the closet or privy. The pail is taken away every day and a clean one left in its stead. Some two miles from the centre of the town there is a vast expanse of vacant marshy ground redeemed from the sea where the sewer outfall is situated close to the pumping-station for raising the sewage. Above the main sewer is a road which stands some 15 ft. higher than the surrounding soil and pools of water. These pools are often 6 ft. deep and into one of them the typhoid dejections are thrown and the pails are then washed. There is no dwelling within a distance of about a mile. The pool will be filled up with earth or road sweepings, and it is solemnly declared that no buildings will ever be erected on this spot; but who can thus foretell the future? Nobody can defend this method of disposing of the typhoid dejections, but it is urged that it is only a temporary expedient pending the construction of a destructor. It is difficult to say why these dejections are not burnt even though there be no destroyer. The sawdust is inflammable; a little naphtha would render it still more inflammable, and it would not be necessary to add much more fuel to make a bonfire which would ensure perfect destruction and purification.

The patients may go to the hospital connected with the workhouse in the Lisburn-road and there are also a few beds for paying patients at the Royal Hospital. It is scandalous that so large and wealthy a town as Belfast should not have proper isolation and fever hospitals. The practical result is that the vast majority of the patients are nursed at home, though in most cases their homes are too small and crowded for such a purpose. The rule is that an officer shall call every two days and leave disinfectants wherever there is a case of typhoid fever. When the patient recovers or dies or is removed to the hospital the house is disinfected.

As a consequence of these measures it might be anticipated that at least those houses where a case of typhoid fever had actually occurred would be put in good order. If the sanitary authorities cannot proceed at once against all the owners of bad property they might in any case enforce the necessary alterations in the houses where cases of contagious fever had occurred. Yet—incredible as it may seem—this has not been done. The last time I was in Belfast I visited some of the worst quarters and houses of the town and described them in THE LANCET. On the present occasion I have visited some of the newest and what are supposed to be the better streets and also some of the houses where there had been cases of typhoid fever and where as a consequence it was to be presumed everything would have been put in order. The result of this investigation was as surprising as it was disappointing. My first visit was to a house in ——street. Here a patient suffering from typhoid fever had been removed to the hospital and apparently the house had been disinfected. It was provided with a water-closet situated in a small back-yard. On lifting the closet seat I saw that there were rat-holes close by the syphon which stood under the pan. On pulling the string to flush the closet I found that the water came out and splashed in the direction of the rat-holes. There was a distinct smell of sewage. The patient was a young woman who had slept in a back room close to this disjointed and leaking closet and the inhabitants of the house complained of the bad smell which came from this place. The yard is carefully paved but it is

Digitized by Google

uneven so that the water does not all flow to the gully leading to the drain. This house, I was informed, stands on made-up ground, formerly a hollow which had been filled up with all manner of filth. The sanitary inspectors could not alter the nature of the subsoil but they might have sought to prevent the ground becoming still more foul by the leakage from a broken or disjointed closet. Close by there is a small shop where bread, cakes, biscuits, bacon, and other articles of food are sold. The owner of this shop had two daughters who had acquired considerable popularity and were much esteemed in the neighbourhood. Both these young women were struck down by the fever and both of them died, and their brother is now also ill. This dramatic occurrence has attracted much attention. The sanitary inspectors have been over and over again to the house. It has been disinfected and lime-washed throughout and after so much and such disastrous sickness it is only natural to expect that nothing would be neglected to render the dwelling more wholesome. Passing through the shop and a small back room I reached the yard. Here a wooden shanty had been built to hold empty cases, and the yard itself was much encumbered with boxes, &c. In fact, the premises are too small for the business, and it would be very difficult to clean out and dust properly a place so crowded with cases and the miscellaneous goods which constitute the tradesman's stock. The closet was in the yard but not far from the bedroom windows. To my great surprise I discovered that in spite of the numerous visits of the sanitary inspectors the pan of the closet was quite loose. It rested on the syphon trap but was not jointed and could be pushed to one side or the other or lifted right off. The trap itself seemed firmly set in the ground and could not be moved, but on flushing the closet I found that some water jutted out beyond the trap and near to the wall at the back of the closet. There were two leakages—one where the pan rested on the trap and the other beyond the trap, probably at the joint between the trap and the soil-pipe. Thus and in spite of the three cases and two deaths from typhoid fever occurring in this house, nothing had been done to put the drains in order, and yet without applying any smoke or water test it was easy to see that they leaked. It is difficult to conceive a more glaring instance of absolute neglect. This is all the more scandalous as the condition of the closet not only endangers the life of the inhabitants of the house but may contribute to contaminate the food sold in the shop to numerous customers. The two houses just described had had cases of typhoid fever and it was for that reason that I visited them. I now, however, entered a house close at hand but selected haphazard without knowing anything of the history of the place, and here again I found that the pan was not cemented on to the trap but was quite loose, wobbled about on being touched, and that a portion of the water of the flush escaped on to the floor of the closet instead of flowing down the soil-pipe.

Going to a neighbouring street composed of very small cottages my attention was attracted by a street door which suggested that the house had been besieged. A portion of the panels had apparently been kicked away. The apertures in this wreck of a door were large enough to admit the passage at least of a child. Inside the house bore an equally ruinous appearance. There was no furniture. A straw mattress on the ground did duty for a bed. There was fæcal matter on the floor inside the house and all over the back-yard where it mixed with stagnant water. There was no water-closet but an overflowing uncovered privy which gave forth the most horrible stench. The next-door house was hardly any better. The front door, it is true, had not been smashed and there was some slight attempt at furniture—a few planks nailed together to imitate chairs. The privy in the back was in a similar condition to that of the house first visited, and fæcal matter mixed with the stagnant water amid the ill-assorted tile flagging of the yard. There was a case of fever in the back room where the window overlooked the stinking uncovered privy, and in the front room a child, six months old, was suffering from congestion of the lungs. The squalor, the dirt, and the stench were appalling. A little further down the same street I noticed a medical man's carriage, or rather it was an Irish jaunting car. I found that there was a child suffering from typhoid fever and that the patient was going to be removed to the workhouse infirmary. This was the third case from this same house and the wonder is that there was anyone remaining in such a place to tell the tale. In the back-yard I saw the same sort of ghastly uncovered privy, but in this instance there was not even the pretence of a closet seat. There was a wall rising some 2 ft. above the side of the hole which constituted the privy and which might have supported a seat, but no seat had been placed there. The yard drain was covered with a plank of wood. It was untrapped. Under the bed in the back room, separated from the yard only by the wall of the house, a large hole could be seen which from time to time was filled up with foul-smelling water that came in from the yard. The boarding of the floor was rotten and there were large holes in it, so that the smell of the polluted earth and foul water beneath reached without hindrance the persons who slept above. Although three cases of typhoid fever have occurred in this house people are still allowed to live in it and nothing has been done to alter this shocking state of affairs. Surely, if a water-closet cannot be put into this house the privy might be cleaned out and rendered watertight, the yard might be properly paved and drained, and measures might be taken to prevent the formation of pools of sewage immediately under the bed in the back room. Now that three cases of typhoid fever have occurred in this house is it not time that some such measures should be taken? To merely whitewash walls and sprinkle disinfectants about is worse than doing nothing. Thus again I found another house in the same neighbourhood where a girl had typhoid fever so severely that little hope was entertained of her recovery. Here the house had been disinfected and whitewashed a day or two before my visit; but the inspector had not examined the closet and yet it was easy to see that the pan was loose, also the inhabitants complained that bad odours came from it. Now from this house, and apart from the case of typhoid fever referred to, a little boy had been removed to the hospital on July 15th last. He also was suffering from typhoid fever, nevertheless nothing had been done to the place before the month of November. In the house next door a part of the yard was boarded over and converted into a stable for horses. Here the water-closet pan was also loose. The pavement of the yard was not firm and squirted up dirty black water when trodden upon. In the house opposite there had been a case of typhoid fever, but in this instance the bed of the patient had been burnt, and this is the only case of effective disinfection I have to record in regard to this neighbourhood.

My next series of visits was to a district which had recently been flooded. Overflows from a main sewer were, I was informed, recently constructed and communicated with the Blackstaff rivulet. But on this particular occasion instead of the sewer overflowing it was the stream which overflowed into the sewer and forced the sewage back into the streets and houses. In a little street consisting of white-washed cottages I visited a dwelling where the privy in the back-yard was on a higher level than the ground-floor living-room. Here the water of the flood rose to a height of about 2 ft. In consequence of the higher level of the back-yard the door leading to it was barely 4 ft. high and it was necessary to stoop considerably to pass through. There was no trap for the yard drain, but a simple hole had been made in the wall which separated the yard from the back passage running behind all the houses. This hole went straight to the drain which passes down this back passage and thus the water and the smell rose freely from this passage drain into the back-yard which only measured some 8 ft. square. To make matters worse 3 ft. of this space were taken up by the privy. Thus the atmosphere was polluted by both drain and privy. When the water of the flood came rushing out of this drain in the back passage and out of the gullies in the street in front it brought all manner of filth into the houses. This occurred during the night and when the inhabitants came down in the dark from their sleeping room they plunged into water up to their knees. On the subsidence of the waters there was an awful stench from the dirt deposited on the floors and walls of the rooms, yet no measures whatsoever were taken to clean and dry these houses. The inhabitants had to do what they could at their own expense. In the house which I visited there had been a case of typhoid fever last August, yet the drain from the yard was left in the condition just described.

Behind a row of houses in —— street I came upon several cowsheds which to my utter surprise I found had been registered—that is to say, sanctioned by the municipal authorities. On one side of this long narrow back-yard was a row of privies which in some cases had been packed to overflowing with stable manure. But there was

Digitized by Google

also a large amount of manure piled up in the yard. Nor was the yard properly paved. There were some rough uneven stones which facilitated rather than prevented the formation of pools of stagnant water and liquid manure. The cows were kept in small, dark, ill-ventilated stables which were not drained to a sewer. The liquid manure from the stables found its way to a small cesspool in the yard outside the stable door. This tank or cesspit was covered only by a wooden door, and if it rained heavily the rain-water which accidentally reached this inefficiently protected cesspit caused it to overflow into the yard. Formerly a man was employed to periodically empty this cesspit and the tenants had to pay 3*d*. a week extra in rent to have this done for them. But the man fell ill with fever and never returned. The tenants have to empty the cesspit themselves, though they still have to pay the 3*d*. per week. The liquid manure taken out of the cesspit is simply poured on to the surface of the yard and then it flows away into a drain which, I was told, is partly a pipe and partly a brick drain. The stench which this operation occasions is so terrible that several inhabitants asserted that they feel sick for the whole day. A woman volunteered the statement that her son had on one occasion emptied the cesspit but he was so ill afterwards that he had not ventured to do it again. When it is remembered that the cows are milked in this yard and amid these foul surroundings the danger of the situation will be better understood. But there was danger of specific as well as of general contamination, for in one of the houses forming part of this yard and where the inhabitants own one of the cows three children have suffered from typhoid fever. In answer to my inquiries I was assured that the children were not removed to the hospital but had remained in the house during the whole time of their illness. They were not even provided with pails, so that their dejections were thrown out into the open privies in the yard and close to the spot where the cows were milked. Yet these stables are registered—that is to say, they are sanctioned and approved by the authorities.

On leaving these abominable stables I came across one of the recent so-called improvements. This consisted of a sewer ventilating shaft going up the wall of a two-storey cottage. It was a 4½ in. pipe made of light metal and terminating about a foot above the edge of the roof. There was a hood placed above the pipe apparently for the purpose of deflecting the odour downwards into a window which was barely 2 ft. below. The inhabitants of the house complained of the bad smell blown down from the pipe through their bedroom window.

(To be continued.)

THE EPIDEMIC OF TYPHOID FEVER IN BELFAST, 1898: DR. LORRAIN SMITH'S REPORT.

(FROM OUR BELFAST CORRESPONDENT.)

WHEN the outbreak of typhoid fever in Belfast reached such a height as to alarm the citizens the Public Health Committee, at the suggestion of the chairman (Alderman Graham, M.D.R.U.I.), appointed Dr. J. Lorrain Smith, Lecturer on Pathology at Queen's College, Belfast, to investigate the cause of the epidemic and as a result that gentleman has for the past few months been busy at work, and as the outcome of this most careful study he has presented to the city corporation of Belfast a most original, able, and thoroughly scientific report. As Dr. Smith points out, as the probable causes of such an outbreak of typhoid fever two factors present themselves. These are: (1) deficiency in drainage and general arrangements for the disposal of refuse and infective material; and (2) possible infection of the water-supply.

As to the first factor, he admits that the insanitary conditions in Belfast which have been pointed out by experts in sanitation are of such a nature as to contribute materially to the spread of the infection from case to case and possibly to originate the outbreak, and especially in a city where typhoid fever is endemic these conditions if left unremedied would render futile any attempts at the extinction of the disease.

As to the second factor (contamination of the water-supply) Dr. Smith shows that there is no doubt that there had been recently cases of typhoid fever in one of the catchment areas and that no precautions were taken to prevent the infection of the water. The problem Dr. Smith set himself to solve was, Did the infected material reach the water-supply and was it in actual operation during the epidemic? This question only a bacteriological investigation would answer and it involved *in limine* the study of the micro-organisms which actually produced the disease. He first endeavoured to discover the cause of the disease in fatal cases and he found by examining the spleen and by making cultivations of the micro-organisms present there that there was evidence of two groups of bacilli which are in structure closely related—viz., the typhoid bacillus of Eberth and the bacillus coli communis of Escherich. The next part of the investigation was to determine the presence of one or both of these in the water, and to carry out this thoroughly Dr. Smith took over thirty samples of water at various infected houses in Belfast and in addition he had an apparatus at work continuously in Queen's College Pathological Laboratory by which he obtained a sample of the water bacteria during September and October. From these sources he failed to isolate the typhoid bacillus, but he had no difficulty in isolating a large number of varieties of the bacillus coli communis. Its presence indicates that the water is polluted with intestinal excreta and its significance in relation to the disease is increased when, in addition to possessing the typical cultural and structural characteristics, it has a high lethal power when injected into small animals, such as guinea-pigs. Certain of the bacilli isolated by Dr. Smith possessed all these characteristics. Now comes the most interesting part of Dr. Smith's report and I quote from his own words: "If this bacillus (bacillus communis coli) is actually a factor in the production of the disease one would expect that the blood of patients suffering from the disease would exhibit a certain reaction of infection to the bacillus known as the 'clumping reaction' (a full explanation of this point is given in the Appendix). On closely investigating the coli bacilli which I had isolated from a typhoid spleen I found that a number of those isolated gave this reaction with the blood of the typhoid patients in a certain percentage of the cases with which the typhoid bacillus had given a reaction. On examining in the same way the coli bacilli from the water it was found that certain numbers of the growth isolated gave the same reaction to the blood of typhoid patients. I have examined the blood of about 200 cases of typhoid fever, including, for the sake of comparison, some other centres (Lurgan and Dublin), and in the time I have had at my disposal I have done my utmost to test the evidence which this line of investigation furnishes, and I have come to the conclusion that we have in the coli bacilli which occur in the water a form of microbe which is directly concerned in the infection of typhoid fever. I give in detail the evidence on this point in the Appendix, but I may state here that 40 per cent. of the cases reacted to the coli bacillus, while at the very highest about 60 to 70 per cent. of the cases reacted to the typhoid bacillus. This latter percentage was obtained with a form of typhoid bacillus which gives exceedingly high results. Typhoid bacilli derived from other sources give fewer reactions. The highest percentage of reactions—viz., from 60 to 70 per cent.—is a low average, but this low average is due to the high standard adopted in the observations." To sum up, Dr. Smith says that the general result of his investigation is: 1. In the presence in the water of the typical bacillus coli communis there is evidence of contamination with intestinal excreta. 2. Certain of these bacilli exhibit their relationship to the process of infection in typhoid fever (*a*) by their lethal effect on small animals and (*b*) by showing the reaction of infection when exposed to the blood of typhoid fever patients. In conclusion, Dr. Smith reports that short of discovering in the water the typhoid bacillus also and thereby giving absolute proof regarding the primary cause of the epidemic he knows of no stronger bacteriological evidence than that which he has adduced in favour of the conclusion that the contamination of the water is one of the causes of the outbreak of the disease in Belfast.

From Dr. Smith's report it will be seen that there are many points of similarity between the epidemics of typhoid fever in Maidstone and in Belfast. In both the water-supply at a certain point was contaminated by typhoid excreta. In Belfast (the evidence is given in the Appendix A of Dr. Smith's report) it would appear that in January, 1897, three

Digitized by Google

or four cases of typhoid fever occurred at a farm at the catchment area known as Stoneyford and portions of the discharges from the patients were thrown into the manure heap the liquid from which flows into the adjoining stream and thence into the Belfast water-supply. This occurred in January, 1897, and in March of the same year the epidemic broke out in Belfast. Dr. Smith thinks it very probable that these cases were the actual origin of the outbreak. Further, he states that from reports received of suspicious cases occurring recently among the inhabitants of the Stoneyford area the matter demands, not only now but as long as the present water-supply is used, the constant attention of the sanitary officers. The second point of similarity between the two epidemics of typhoid fever at Maidstone and Belfast is that in neither case did observers find the specific typhoid bacillus in the water, while at Maidstone as well as at Belfast the bacillus coli communis was present in abundance. In criticising the reports of those who examined the water at Maidstone Dr. Sims Woodhead stated that the presence of the bacillus coli communis should be regarded as evidence of contamination provided that the bacillus had certain biological characters and was pathogenic to animals. Certain of the bacilli isolated from the Belfast water, Dr. Smith states, answer to all Dr. Woodhead's criteria. There is, however, one point of distinction between Maidstone and Belfast, and that is the very important fact which Dr. Smith admits that in Belfast typhoid fever is endemic. From Dr. Smith's report there naturally follow two practical suggestions: (1) the Water Commissioners must take greater care in reference to their catchment areas and they must specially look to it that in their new works in the Mourne Mountains as well as in the reservoir at Carryduff the utmost precautions shall be put in force to prevent the least trace of local contamination; and (2) because this report of Dr. Smith seems to put the cause of the outbreak of typhoid fever on the infected water-supply the Public Health Committee must not think that they have nothing more to do than to blame the Water Commissioners. They must remember that their own expert and adviser, Dr. Smith, states in his report that "the insanitary conditions in the city which have been pointed out by experts in sanitation are of such a nature as to contribute materially to the spread of infection from case to case and, possibly, to originate the outbreak and, especially in a city where typhoid is endemic, these conditions if left unremedied would render futile any attempts at the extinction of the disease." The duty of the Public Health Committee is to push on with the sanitary reforms which they have already, I am glad to say, inaugurated, no matter what the cost may be, so that the disease may cease to be endemic.

In the Appendix to his report Dr. Lorrain Smith deals with: (*a*) observations on the catchment area at Stoneyford; (*b*) methods of analysis; (*c*) the number of bacteria present in the water; (*d*) the reaction of infection known as "clumping reaction"; and (*e*) the bacillus coli communis.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Sittings of the Plague Commission.—The Bombay Improvement Scheme.—The Pasteur Institute at Hyderabad.—The Faulty Administration of the Plague Regulations.

IT must be admitted that the sittings of the Plague Commission have not so far resulted in discovering anything new. The four days' examination of certain prominent officials has only reproduced what was known twelve months or more ago and what has all been published before. The Commission consists of Professor T. R. Fraser, M.D.Edin., LL.D., F R.S., Professor of Materia Medica in the University of Edinburgh, president; Mr. J. P. Hewett, C.I.E., I.C.S., Secretary to the Government of India, Home Department; Professor A. E. Wright, M.D. Dub., Professor of Pathology in the Army School, Netley; Mr. A. Cuming, I.C.S., of the Bombay Presidency; Dr. M. A. Ruffer, of the Egyptian Sanitary Department; and Mr. C. J. Halifax (secretary). The object with which the Commission has been appointed is—as was stated in the Government resolution—to inquire into the following questions: (1) the origin and outbreaks of plague; (2) the manner in which the disease was communicated; (3) the effects of the curative serum; and (4) the effects of the preventive serum. Many acute observers have already formulated their knowledge on these points and have expressed their opinions that plague in man is communicated from the lower animals and probably in most cases from the rat; that it extends chiefly by the spread of the disease among the lower animals but that the habitation in some way also becomes a source of infection; that, so far, no serum possessing curative properties can be said to have been discovered but that the preventive fluid has decided powers to diminish the liability to infection as well as to diminish the risks of the disease amongst the inoculated.

The first day was occupied with the examination of the Hon. Mr. Wingate (the Plague Commissioner) and of M. Haffkine. The evidence of the former consisted in giving a brief outline of the epidemic and of its spread to different parts in the Bombay Presidency. He enumerated the several measures adopted by Government with the aid of local bodies to check its progress and minimise its effects. Information on this head has already been published in a very comprehensive Government Report by Mr. Nathan. M. Haffkine explained the process of preparing the plague prophylactic fluid and the experiments first conducted to test its efficacy. He also laid before the Commission some statistics to show its results.

On the second day M. Haffkine gave further evidence concerning inoculation, its effects on different individuals, the dose, the method of cultivating and sterilising plague bacilli, his early curative serum, and its failure. He stated that he had not succeeded in detecting the plague microbe in rooms occupied by plague patients, but that experiments were *now* being conducted on the effect of exposure on artificial cultures in houses where the roofs had been removed, also as to the efficacy of disinfectants and the effect of cowdung on the microbes, and the duration of their life within it. He argued that there was no evidence to show that inoculation increased the sickness or death-rate from general causes amongst the inoculated. He stated that his researches had been restrained by consideration for the popular feeling with regard to experiments on animals.

On the third day Surgeon-General Bainbridge was examined. He candidly admitted that his experience was largely derived from official reports. He thought more laboratory inquiry was wanted. (This seems a curious statement because there were many men experienced in bacteriology and well able to perform this work, who were sent out from England for plague duties and to whom Surgeon-General Bainbridge in his official capacity might have entrusted this investigation.) With regard to the connexion between rats and plague, what he could say was that the rats were generally affected by plague and that before the outbreak in man the rats became ill and died. The attacks on human beings followed very closely. He supported the recognised sanitary measures—the isolation of the sick, the segregation of the occupants of infected houses, the cleansing and disinfection of the houses, the examination and detention of travellers, and the disinfection of persons. He now accepted inoculation as a prophylactic, although at the outset he was unwilling to do so. Dr. Galcott, representing Professor Lustig, explained the method of preparing his serum and gave some results obtained at several hospitals. He admitted that the results were not very satisfactory up to the present time. Dr. Viegas described how he observed and reported upon the earliest cases which had been discovered in Bombay.

On the fourth day Colonel Weir, health officer to the Bombay Municipality, was examined. He gave a description of the sanitary conditions under which the masses of the people lived and referred to the very limited powers which the Corporation possessed under the Municipal Act. He dwelt particularly on the overcrowding, to which there was no limit. He pointed out the course which plague took in spreading throughout the city and gave numerous statistics. He described how the measures at first taken were thought to be unnecessary and cruel. He expressed his belief in the destruction of rats in order to prevent the development and spread of plague. He showed the incidence of plague amongst the dwellers on the different storeys of the large *chawls*—the percentage of deaths to attacks being on the ground floor, 84; on the first floor, 74; on the second floor, 67; on the third floor, 59; on the fourth floor, 48; and on the fifth floor, 45. He strongly supported inoculation against plague and had done so from the commencement.

The Improvement Trust has begun work and promises to effect very great changes in the sanitary condition of

Digitized by Google

Bombay. Several schemes of improvement are ready and one of them is likely to come up for sanction almost immediately. The proposal is to buy up the whole property of one large and thickly populated district—not one street only but a large area. Money will be raised by loan on the land of the properties, the houses will be pulled down and new and wider streets will be laid out, while sanitary dwellings will be constructed to replace the present overcrowded *chawls*. One district only will be taken at a time. While this is being done the people will be turned adrift to find accommodation wherever they can, but it is anticipated that the displacement of the people will not be of long duration. It is obvious, however, that other districts will be excessively overcrowded for the time being and that a twelvemonth at least must elapse before the new buildings will be ready for occupation. Probably also 25 per cent. of the population of the given area will have to find permanent accommodation elsewhere. The distinguishing feature of the new trust is that it can deal with large areas. The rebuilding of houses for 20,000 evicted people cannot be done in a day.

Notwithstanding the detailed account of the proposed Pasteur Institute for Hyderabad which was published apparently on high authority I have it from the Secretary to the Nizam's Government that the question has not yet been laid officially before the Government.

The public are still put to considerable annoyance from the irregular manner in which the plague regulations are enforced. There is no uniformity even in the same Presidency and travellers are subject to all sorts of inconveniences from ignorance of the varying regulations. At Poona the local authorities have been acting contrary to the recent pronouncement of the Government of India concerning the abolition of passes and detention camps, and besides enforcing passes have been offensively huddling together different classes of passengers and insisting without discrimination on the disinfection of all clothes and wearing apparel. In Madras the officials have actually prosecuted the Postmaster-General for a purely technical breach of the plague regulations notwithstanding that he had been inoculated and that the offence committed was practically cleared by the fresh regulations which appeared on the day of his prosecution. These are examples of the want of business-like administration which has characterised the plague work from the very beginning. The management is placed in the hands of civilians or military men instead of with medical officers, and the consequence is that these exceptional powers have been exercised in a high-handed and indiscriminate manner.

Dec. 3rd.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Mill-road Infirmary: Opening of a New Operating Theatre.

THE new operating theatre at the Mill-road Infirmary was formally opened last week in the presence of a large gathering of guardians and members of the medical profession. The theatre is situated in the upper storey of the building and is constructed upon highly approved scientific principles. To the right is the anæsthetic room whence the patient will be wheeled on an ambulance into the operating room. The theatre is well lighted by a large roof, the light facing south and west. The walls are lined with white glazed tiles and the floor is of marble, sloping to a sink for flushing purposes. Needless to say that artificial lighting is by means of electricity, the current of which is also utilised for medical and surgical purposes. All the instruments for use in operations will be sterilised and the dressings before being applied will also be sterilised by drying heat at a temperature of 220° F. Injectors for the supply of absolutely sterile water are provided and all the wash-basins are fitted with foot-pedals, thus obviating the necessity of touching the taps with the hand. The instruments are kept on glass shelves in a dust-proof case to ensure absolute cleanliness and to carry out the aseptic system of surgery. An average of 250 major operations are performed in the infirmary annually. After the inspection the company sat down to luncheon at the invitation of Dr. N. Raw, the medical superintendent. Professor Paterson of University College, who was one of the guests, in proposing the toast of "The West Derby Board of Guardians" complimented the board on the excellent work they were carrying out in the administration of the Poor-law and in their treatment of the 850 sick poor in the Mill-road institution in particular. Alderman Houlding (the late Lord Mayor of Liverpool) and Mr. Mitchell Banks also spoke in complimentary terms of the admirable arrangements made by the West Derby guardians for the comfort and treatment of the sick poor of their union.

Medical Faculty of University College, Liverpool.

The biennial dinner of the Medical Faculty of University College will be held on Jan. 28th, 1899. Professor A. M. Paterson, the Dean of the Medical Faculty, is particularly desirous of making the re-union a most successful one.

Ladies' Charity and Lying-in Hospital: the Proposed Admission of Unmarried Females.

I understand that summonses have been issued for a general meeting of the subscribers to the Ladies' Charity and Lying-in Hospital which has been fixed for an early date, when the question of the admission of unmarried females (about to be confined) to the wards of the lying-in hospital will be discussed in all its bearings. There is every reason to believe that the subject will be treated in a broad and generous spirit and that a long-deferred concession in the case of first confinements is within measurable distance of realisation.

Centenary of the Liverpool Athenæum.

The centenary of the Liverpool Athenæum was celebrated on Dec. 19th under auspicious circumstances. The programme of the proceedings included an address by the Lord Bishop of London and a reception afterwards in St. George's Hall. The Athenæum owes its foundation to the late Dr. James Currie, the biographer of Robert Burns, the late Dr. Rutter, Mr. Roscoe, and a few other prominent citizens of Liverpool, to whom a graceful tribute of admiration was paid by Mr. Alfred Booth, the President, in his introductory remarks relating to the history of the institution. The Athenæum contains a well-stored library in which are to be found many rare and valuable works. It is situated in a central part of the city in Church-street and numbers 500 members, largely recruited from the cream of the mercantile and professional classes.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

"*Glasgow Medical Pioneers.*"

AN address on this subject to the Anderson's College Medico-Chirurgical Society was delivered on Dec. 17th by Dr. Erskine, honorary president of the society. The lecturer gave a history of the leading local medical authorities since the institution of the Faculty of Physicians and Surgeons at the end of the sixteenth century. In connexion with this event there was necessarily special reference made to Maister Peter Lowe who was in his day physician to Henry IV. of Navarre and to Prince Henry, son of James I., and to whom the foundation of the Faculty is due. The work of Cullen when professor of medicine in the university and of John Burns, the first professor of surgery, was also discussed and allusion was made to the special local associations of the brothers William and John Hunter. Among other interesting particulars in connexion with the Royal Infirmary note was taken of the work of Dr. Robert Perry as one of the first to establish an essential distinction between typhus and typhoid fever. The same institution could also claim the establishment by Lord Lister of the antiseptic treatment of wounds and more recently the surgical triumphs of Dr. Macewen. Professor Moses Buchanan and his son, the present professor of clinical surgery, and Professor Allen Thomson were among others on the roll of fame, whilst the lecture was brought up to date by a description of the valuable sanitary work performed by Sir William Gairdner and Dr. J. B. Russell. The address was illustrated by lantern pictures, and was much appreciated by the audience.

University of Glasgow.

The special committee appointed to consider the development and extension of the medical school has proposed a scheme for the provision of a pharmacological laboratory and the proposal has received the approval of the University

Court. It has also been decided to permit women to attend post-graduate classes in the medical faculty. Mr. D. C. M'Vail, M.B. Glasg., has been appointed to represent the court on the board of managers of the Glasgow Samaritan Hospital. The court has also approved of the nomination by the Senate of Mr. Hugh Galt, M.B., C.M. Glasg., to be a research fellow in the University.

Glasgow Sanitavy Department.

The recommendation of the health committee that Dr. A. K. Chalmers shall succeed Dr. J. B. Russell as medical officer of health and that an assistant medical officer shall be appointed has been approved by the town council.

Presentation to Mr. John Burns, Glasgow.

A long record of honest and unassuming work was recognised yesterday by the presentation to Mr. John Burns of his portrait, painted in oils by Mr. John P. Downie. Mr. Burns has for nearly sixty years been in practice in the East-end of Glasgow, and for that, as well as for other reasons, is one of our best known local worthies. The presentation was made on behalf of the subscribers by Sir William Gairdner who referred in eulogistic terms to the personal and professional merits of Mr. Burns and emphasised the value of his work and influence. In reply Mr. Burns acknowledged in feeling terms the kindly recognition accorded to him and related a number of interesting particulars of his Glasgow memories and associations. In the evening he was entertained to dinner at the Windsor Hotel. The portrait which is of life-size is to be placed in the custody of the Corporation and is to be exhibited in the People's Palace.

Typhoid Fever in Aberdeen.

There has just occurred in Aberdeen another outbreak of typhoid fever—19 cases with 2 deaths—which like the last has been traced to infection by milk.

University of Aberdeen.

The portrait of the Marquis of Huntly, Lord Rector of the University, painted by Mr. J. Coutts Michie, A.R.S.A., has been placed in the picture gallery at Marischal College. The portrait is the gift of the artist.

Aberdeen Medico-Chirurgical Society.

The annual dinner of this body was held in the society's hall, King-street, Aberdeen, on Dec. 16th. Dr. Thomas Milne of Ellon, president, occupied the chair, and there was a large attendance of members and guests. Professor Stephenson (Aberdeen University) was croupier. The President gave the toast of "The Medico-Chirurgical Society." Dr. Ashley W. Mackintosh replied for the "Navy, Army, and Reserve Forces," and Professor Findlay for "The University and Medical School." Professor Stephenson replied to the toast of "The Medical Charities," and Dr. Angus Fraser gave that of "The Founders of the Society." Dr. Edmond proposed "The Guests," coupled with the name of Dr. Wilson of Huntly. The speeches were happily interspersed with amusing anecdotes.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Regius Professorship of Physic, Dublin University.

DR. JAMES LITTLE has been elected Regius Professor of Physic of the University of Dublin in the room of Sir John Banks, resigned.

An Irish Patent Medicine Bankruptcy Case.

Of all the secret and patent medicines sold in Ireland the one most widely advertised of late years has been that known as "Trench's Remedy." It was a nostrum recommended for the cure of epilepsy, and was generally supposed by medical men to be a strong solution of the bromides. There is no doubt that the medicine was largely given away for purposes which seemed entirely charitable. In the Bankruptcy Court, on Dec. 9th, the case of J. Townsend Trench, a bankrupt, was heard by Judge Boyd. Mr. John Bernard, pharmaceutical chemist, of Clare-street, deposed that he had an arrangement for a number of years to supply the bankrupt with drugs and that he, witness, looked for a profit of from 10 to 15 per cent. It was proposed in last December that as Mr. Trench could not meet his liabilities a company should be formed and that the amount of the debts—viz., £9500—should be the amount of the purchase money. Mr. Trench is a man of considerable private property.

The Belfast Water-supply.

The Belfast Water Commissioners are about to promote in Parliament a Bill to authorise them among other things to construct certain works for the improvement and extension of their water-supply, and for this purpose to acquire and purchase large tracts of land in the neighbourhood of Carrickfergus and Stoneyford, at their catchment areas. As a result the farmers who will be affected by the proposed Bill are arranging to oppose it and an important meeting of those affected by this compulsory purchase of their homesteads was held on Dec. 17th in Carrickfergus at which those present pledged themselves to oppose in Parliament the proposed scheme of the Belfast Water Commissioners, a plan which they characterise as "iniquitous and most unjust as it is based on misleading and erroneous statements regarding the pollution of their water-supply." It is reported that those living in the Stoneyford catchment area will also join in this opposition. I think the Water Commissioners under very difficult circumstances are doing their best. They have been forced by public opinion to take the utmost precautions to keep their present supplies free from the risk of any pollution. This can only be done by safeguarding the catchment areas, and now when they are presenting a Bill for this purpose the farmers resident in the area (and there is nothing that an Irish farmer resents so much as forcible eviction even with compensation) threaten them with what in law will be a very awkward opposition to their measure. The absolute necessity for the Water Commissioners to take the proposed precautions at Stoneyford is still more strengthened by the published report that at the last meeting of the Lisburn Board of Guardians, Dr. Alexander, medical officer of Knocknadona dispensary district, reported that a case of typhoid fever recently occurred in a house near a river flowing into the Stoneyford reservoir and that the excreta from the patient were thrown on the manure heap without being disinfected. Dr. Alexander very wisely recommended that this manure should be removed by the Belfast Water Commissioners out of their catchment area, as being liable under certain conditions to contaminate the water. The guardians ordered that a copy of this report should be sent to the Belfast Water Commissioners.

The Belfast District Lunatic Asylum.

A deputation from the governors of the Belfast Lunatic Asylum met the finance committee of the city corporation on Dec. 19th to consider some important monetary matters. It was explained by the governors that the Board of Control of Asylums in Dublin made a demand from the corporation of £400, amount of fees due to the architects and surveyor in respect of the new Purdysburn Asylum. The finance committee of the corporation replied that they considered it strange that the Board of Control did not think it necessary to place before the corporation any details regarding the plans which had been prepared and the final amounts which they would be required to meet. In the absence of any statement regarding these they decided not to make an immediate advance of money, but to ask the Board of Control for further information on the points mentioned.

(FROM OUR OWN CORRESPONDENT.)

Medical Men Prosecuted by a Confrère.

DURING the course of a trial held in September it came out in evidence that Dr. Choisnet of La Flèche had through negligence given the accused woman a certificate to say that she had not been recently delivered. The other medical men in La Flèche (five in number) accordingly wrote to Dr. Choisnet a letter which they also published saying that they considered him as no longer belonging to the medical body and demanding the erasure of his name from the list of those entitled to serve on public bodies. Dr. Choisnet prosecuted his five colleagues before the Correctional

Digitized by Google

Tribunal of La Flèche and eventually they were condemned to pay a fine of 100 fr. respectively and to pay collectively 1000 fr. damages.

A Medical Trial.

A trial is about to be heard in which the facts possibly are not new but, it is believed, are to be submitted to a legal tribunal for the first time. Two years ago a patient was attended in her confinement by her usual medical attendant, but not recovering in a normal way she underwent an operation performed by a young surgeon who had been a pupil of Péan. The operation seemed to do no good and the patient still kept her bed. Despite the entreaties of the surgeon that she should have a second operation, she would never consent and fifteen months after the first operation she went into the Hospital of St. Louis where a laparotomy was performed by Dr. Marchand. In the course of this operation a Hegar's dilator (bougie) made of metal was discovered which had been overlooked by the first operator. Questioned on the matter the young surgeon admitted the facts and added that that was just the reason why he had urged the second operation—namely, to get rid of the dilator. The patient who is now quite well has commenced proceedings against her medical attendants for malpraxis.

A Touching Ceremony at the Hospital of St. Louis.

The inauguration of a memorial erected by public subscription to the memory of Dr. Henri Feulard took place recently in the library of St. Louis Hospital. The pedestal, carved by the sculptor Maurice Bouval, is very simple and dignified. The statue, cast and bronzed (*patiné*) by Siot-Decauville, stands under a canopy of *rouge antique* marble which was designed by the architect Michelieu. Sundry allocutions were given in the presence of the subscribers, friends, and colleagues of Dr. Feulard. The ceremony was a really heartfelt manifestation of the respect in which Dr. Feulard was held. It will be remembered that he perished owing to his devoted conduct at the lamentable fire at the Charity Bazaar last year.

Mushroom Juice as an Antitoxin against Serpent Venom.

M. Phisalix gave the result of some experiments which he had made on the use of mushroom juice as an antitoxin against serpent venom at the meeting of the Academy of Sciences held on Dec. 12th. He first of all pointed out that tyrosin, which is the chemical nucleus of all albuminous bodies, when extracted from the juices of serpents, is an immense power against their venom. He said that he had been led to seek whether the juice of mushrooms which contains plenty of tyrosin and some ferments as well would not possess the same properties. He made various experiments and found out that all kinds of mushrooms possess a substance which acts as an antitoxin against serpent venom. If, for instance, the juice of the ordinary hot-bed mushroom is extracted by pressure or by maceration in water and inoculated into a guinea pig the animal is rendered absolutely refractory to serpent venom. Unfortunately, however, the inoculation seems to possess toxic properties which vary in degree according to the size of the dose. In the rabbit, for instance, the injection of 25 c.cm. of mushroom juice is fatal, the animal dying from intervascular coagulation. With a view to avoiding these results M. Phisalix tried filtering and boiling the juice, but all the same the toxic properties remained although they were much diminished.

Fat in the Horny Layer of the Skin.

At the meeting of the Academy of Sciences held on Dec. 5th M. Ranvier put forward the idea that the horny layer of the skin is infiltrated with fat. This epidermal fat is of a yellow colour and solid at ordinary temperatures. It has the consistency of wax and melts at a temperature of about 36° C., just as beeswax does, with which it presents a very close analogy, an analogy all the more interesting because beeswax, like the similar substance found in mammals, is a secretion of the skin. The cells of the horny layer of the epidermis, far from being dried up, as is generally taught, are really hollow cells altered in shape by reciprocal pressure. Their walls are formed by a resisting substance and the contents are waxy. Owing to the mode of distribution of the epidermic wax in the horny layer of the skin it is obvious that the entire body is covered with a kind of varnish, and thus it is protected against both mechanical injuries and chemical injuries.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Excessive Cold.

THE steady fall in the temperature is felt severely throughout the peninsula. In northern Italy, particularly on the Adriatic side, Rovigo, for example, in the twenty-four hours between 8 A.M. of Dec. 15th and 8 A.M. of Dec. 16th registered 3° C. below zero; Mantua, 2°; Ferrara, 1·5°; Ravenna, 1·4°; and Belluno, 0·9°. In Central Italy Florence registered a minimum of 1·1° C. and a maximum of 7·5°. But it is in the southern provinces that the cold, which between Dec. 16th and 17th increased so suddenly, has numbered most victims. "Miseria"—that comprehensive word which includes starvation, semi-nudity, homelessness, and despair—is rampant in the ex-kingdom of the Two Sicilies and there, of course, the fall of temperature finds multitudes in town and country with a resisting power quite unequal to the visitation. In Naples three deaths are already announced as having occurred in the streets on Dec. 17th and many more may be expected according as the reports come in from the police offices and hospitals. Italians, as a rule, stand extremes of temperature wonderfully well—cold particularly. Of all the contingents of the Emperor Napoleon's Grande Armée in the disastrous retreat from Moscow in 1813 Murat's 10,000 Neapolitans suffered least from the frost-bite or from the numbness and the torpor which, in the case of thousands of their non-Italian comrades, lapsed into the sleep that knows no waking. The fact gives a measure of the "miseria" which has prepared so many victims in the Neapolitan districts within the last forty-eight hours. The season, as a whole, has commenced badly for the Mediterranean littoral and that means, in Italy *par excellence*, lack of custom for the many interests which profit by the moneyed visitor. Not only on the Riviera Levante as well as on the Riviera Ponente are the hotels all but empty, but in such favourite resorts as Florence, Rome herself, and Naples a similar tale is told. Impecuniosity and pauperism are intensified and with them the "miseria" that decimates the lower strata of society. The prevalence of abnormal cold and the menace of a severe winter will deter yet more the hitherto tardy tourist- or travelling-world and so the situation, financial and social, must become aggravated. Nowhere more than in the "genial South," particularly in those sun-traps which nestle along the Neapolitan Riviera, will it be said with the poignancy of truth, "Sadly falls our Christmas Eve!"

Tuberculosis of the Thoracic Duct.

At the last meeting of the Reale Accademia di Medicina of Turin Dr. Pio Foà, Professor of Pathological Anatomy in the University, drew attention to tuberculosis of the thoracic duct. Whence the tuberculosis had its point of departure was not, he said, very clear. Some of the abdominal ganglia around the cœliac trunk he found to be caseous. The tuberculosis seems to have gained access to the cisterna chyli (reservoir of Pecquet) and to all the thoracic duct which was, nevertheless, quite permeable. The duct in some tracts was extremely dilated and had its parietes greatly thickened and in the light showed an eruption of nodules large and small. There was further a miliary (granular) tuberculosis confined to the two lungs, but as the intromission of bacilli into the blood from the thoracic duct was probably affected "interpolatamente" (at intervals) so there followed an eruption of nodules in the lung at different stages of development. There were, in fact, chronic granulations (*miliari cronici*) and recent granulations, as well as many sub-granulations of quite recent standing. The patient died in consequence of profuse and uncontrollable epistaxis.

The Influence of X Rays in Lupus.

AT a recent meeting of the Vienna Medical Society Dr. Schiff showed a case of lupus erythematodes in which the x rays had been made use of. At the beginning of the treatment the disease existed over the whole face. The rays were

Digitized by Google

employed for two months and the effect is that the infiltration of the skin has entirely disappeared; the surface of the skin is smooth without elevations and the disease is now limited to some discrete isolated patches. In the treatment of lupus vulgaris by means of the x rays Dr. Schiff has met with very gratifying results which have also been obtained by Dr. Finsen of Copenhagen under a different system—viz., by the use of concentrated sunlight or concentrated electric light. This latter method, however, is only applicable to small patches of the disease in question and for extensive surfaces the x rays are to be preferred. Dr. Spiegler, who had seen Dr. Finsen's method put in practice, said that it can only be recommended in cases where the disease is confined to small areas; it never causes the lesions of the skin which sometimes follow exposure to x rays. Dr. Schiff, in his reply, said that the injury to the skin by the x rays may be avoided if the intensity of the radiation does not exceed a certain amount and if the treatment is discontinued on the appearance of the slightest hyperæmia. Professor Kaposi remarked that it was interesting to observe that pathological processes histologically so different as lupus vulgaris and lupus erythematodes both improve under the same treatment. The effect depends on the circumstance that there occurs first an active and then a passive hyperæmia—a paresis of the superior and the inferior vessels of the skin respectively. It is also possible that a chemical action may be exerted directly on the diseased structures, causing them to undergo retrogression.

Heroin.

Dr. Weiss has published in the *Heilkunde* an account of his experience with the new remedy heroin. He has found it very beneficial in chronic bronchitis attended by swelling of the mucous membrane, for after a dose of 5 milligrammes (about $\frac{1}{12}$ gr.) the cough decreases and the pain in the chest disappears. It gave relief in cases of chronic bronchitis where codein had no effect. In phthisis it is an excellent substitute for morphia; 5 milligrammes given three times a day relieve the cough and the pain in the chest.

Dec. 20th.

Obituary.

CHARLES JOHN HARE, M.D. CANTAB., F.R.C.P. LOND.

ONE of the old school of practitioners has passed away in the person of Dr. Charles Hare. He died on Dec. 15th at his residence, Berkeley House, Manchester-square, from carcinoma of the œsophagus, at the ripe age of eighty-one years. Charles John Hare was the son of Samuel Hare, F.R.C.S., who was for many years a surgical practitioner at Leeds and who died in 1867. Dr. Hare received his medical education at the University of Cambridge (where he graduated as M.B. in 1841, proceeding to M.D. in 1847), at University College, London, and at Paris. In 1850 he took the Membership of the Royal College of Physicians of London, being elected Fellow in 1859.

Although commencing his medical studies at Cambridge Dr. Hare took the (in those days) very unusual step of migrating to University College, London, where he continued the study of medicine, and he also visited Paris with the same object. His connexion with University College Hospital dates from the year 1850 when, along with the late Sir William Jenner, he was elected assistant physician. In 1860 he was allotted beds for in-patients to the number of four, being also appointed physician, but he does not seem to have had charge of a ward until the year 1862 when he was given the charge of the in-patients who had been previously under the care of Dr. Garrod. In 1863 he was appointed Professor of Clinical Medicine and in the following year, 1864, attended on his death-bed a certain Mr. Edward Yates of Etchingham, Surrey. We mention this fact because it has an important bearing upon the fortunes of the hospital. Dr. Hare was Mr. Yates's executor and very intimate friend and it was in great measure owing to this latter fact that Mr. Yates bequeathed £46,000 to the hospital. The income of one-half of this was applied to the general purposes of the hospital and the other half was to form a Samaritan Fund. This fund was duly started in 1867 and out of it patients are sent to convalescent homes, their families are supported while the bread-winner is in the hospital, surgical appliances are procured, and dinners are provided for such patients as need them more than medicine. In this year Dr. Hare found it necessary to terminate his connexion with the hospital which he had served for seventeen years—that is, so far as active work in the wards was concerned—for he never lost his interest in the institution and was a member of the hospital committee from 1861 until almost the day of his death. Upon his resignation of the physicianship and professorship both the council of the college and the committee of the hospital passed cordial votes of thanks, the latter specially referring to the services rendered by him in connexion with the Yates bequest.

In 1863 he married Catherine, the youngest daughter of Mr. E. Westhead, of Croston Tower, Cheshire. Dr. Hare was a man about whom not much was known outside the ranks of his immediate friends. He was very kindly, well read, and preserved to the last the dignified courtesy of the old school, together with the professional costume of the early "fifties." He had indomitable pluck and although months before his death he knew the nature of his complaint his spirits and courage never deserted him. One of his friends met him at the University College Hospital dinner on the opening of the present session to whom, in answer to some inquiry concerning his health, Dr. Hare said: "Well, I oughtn't to be here at all. You see I've got cancer of the œsophagus and I can hardly swallow anything. But I know I can't last long, so I want to go on as long as I can."

Dr. Hare, as is not unusual in men who have reached an advanced age, was somewhat a *laudator temporis acti*. Many will remember his trenchant little *brochure* entitled "Good Remedies out of Fashion," in which he strongly urged the claims of emetics, bleeding, and free purgation. No doubt these therapeutic measures have been abused in the past, but equally nowadays they are too much neglected. Although he never attained a very prominent position he was a most admirable clinical teacher, especially upon the somewhat difficult subject of abdominal diseases. He was uniformly kindly and courteous and always ready to help not only with advice but with more material aid those who were in trouble.

A friend of the late Dr. Hare and a representative member of the profession sends us the following words of appreciation: "Dr. Charles Hare had fully completed his years which were full of honour and of happiness—the happiness which consists in having lived usefully, methodically, and genially, with an eye to the happiness of others as well as his own. In many respects Dr. Hare was a model of what a physician should be. He had an abundant fund of common-sense and a very sound knowledge of his profession and of different systems of medical practice, his life having been long enough to see in full force the old treatment and the new and his mind being broad enough to accept what was true in both. But his culture was not confined to medical subjects. His knowledge of men and books and things was wide. He travelled much and with much method and observation. One of the oldest and one of the most highly esteemed of Cambridge medical graduates, he was much regarded by his university and especially by medical graduates. But he was bound by no academic limits and he took a large interest in the profession and in its prosperity, as well as in all public and political questions, expressing himself with the combined frankness and urbanity which are the great notes of true culture and which secure the respect of all sorts and conditions of men. But what most endeared Dr. Hare to those who knew him and gave additional force to the grief felt at the announcement of his death was his unfailing cheerfulness. It was an inspiration and a pleasure to meet him. In all men this is a precious gift, in the physician it is invaluable. In Dr. Hare it was always in evidence, even in late years, when symptoms of physical ill which might have disturbed the serenity of some men asserted themselves in his fine constitution. I have still before me the New Year's card for 1898 which he sent me. It may well serve for any successive year which the youngest member of the profession may see.

'1898.

'Take thy New Year with thankfulness—but is it not well, starting afresh with hope and trust, to commence a new year every morning, determining to leave, as far as may be, all worries (which "have killed their thousands") and all troubles and vexations to the last year's account—closed the night before?'

The sentiment was at once the expression and the secret of Dr. Hare's bright life: it was the practice of this happy philosophy that made him useful to his fellow-men."

CHARLES EGERTON FITZ-GERALD, M.D. ST. AND., M.R.C.S. ENG.

BY the death of Dr. Fitz-Gerald who passed away on Dec. 11th Folkestone loses her oldest and most prominent practitioner. Dr. Fitz-Gerald was born in 1830 and was educated up to the age of fifteen years at a school in Brighton. On leaving school he was apprenticed to a surgeon at Bicester where he remained until he entered as a student at St. Bartholomew's Hospital. He became M.R.C.S. in 1856 and in the same year accompanied the present Marquis of Dufferin on his cruise to the north, the journey which forms the basis of that delightful book, "Letters from High Latitudes." On his return he commenced practice in Folkestone as a partner of the late Dr. Eastes and in 1858 he married. After having been in partnership a few years he commenced practice by himself under a friendly agreement with Dr. Eastes. In 1862 he graduated as M.D. at the University of St. Andrews. He was extremely popular, and in addition to his more strictly professional studies took a great interest in natural history, being the founder and for twenty years president of the Folkestone Natural History Society. The subject of the prevention of tuberculosis interested him deeply and in February, 1898, he read a paper on the subject dealing mainly with the precautions adopted in New York. He was a frequent contributor to our columns and the last paper from his pen which we published appeared so recently as Oct. 8th, 1898. He was buried on Dec. 14th at the Folkestone Cemetery, the first part of the service having been said at Christ Church. He was unceasing in his efforts to promote the well-being of Folkestone and contributed greatly towards its popularity as a health resort. He was an earnest and consistent Churchman, but all the same numbered among his friends many of other denominations and those who differed widely from him in matters of religious belief. As to the estimation in which he was held by his fellow townsmen we cannot do better than quote the closing lines of a leading article in the *Folkestone Herald* of Dec. 17th: "He has left behind the fragrance of a blameless life, the incentive to noble exertion, and above all the sentiments of gratitude which the inhabitants of a town must ever feel for work of such a high character as that which has been done for them by the distinguished physician whose death we are all deploring."

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Jodko-Narkiewicz, one of the most eminent of Russian ophthalmic surgeons. He studied in Dorpat and Warsaw and subsequently held official posts in the latter university. He was sixty-eight years of age.—Dr. Caselli, Professor of Clinical Surgery in the Genoa Medical School.—Dr. Junge, formerly Professor of Ophthalmology in the Military Medical Academy, St. Petersburg.

Medical News.

UNIVERSITY OF OXFORD.—At the first M.B. examination the following candidates were successful in the subjects indicated:—

Anatomy and Physiology.—C. L. Coode, Hertford; V. S. Hodson, Marcon's Hall; G. A. Jones, Magdalen; and A. E. A. Loosely, Pembroke.

Organic Chemistry.—P. E. H. Adams, Exeter; C. V. Aitchison, Balliol; L. H. Badcock, Trinity; J. M. Bickerton, Merton; A. W. S. Fisher, New College; A. F. Hertz and F. P. T. Hilliard, Magdalen; V. S. Hodson, Marcon's Hall; F. Howson, non-collegiate; A. C. Inman, Wadham; H. W. Kaye, Magdalen; H. L. Laws, Wadham; H. C. Lecky, Christ Church; R. S. Macgregor, Exeter; C. F. Pinching, St. John's; P. F. Tinne and H. M. Turnbull, Magdalen; A. J. Wigmore, non-collegiate; E. A. G. Wilkinson, University; and H. M. M. Woodward, Keble.

Final M.B., B.Ch.—O. Eichholz, Magdalen; F. E. Fremantle, Balliol; E. Hopkinson, Trinity; R. O. Moon, New; R. W. Payne, Christ Church; E. H. Scholefield, New; E. W. Walker, Christ Church; S. Welby, Trinity.

Diploma in Public Health.—A. L. Ormerod, New; C. A. Reynolds, Keble; E. A. Saunders, St. John's.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore (Johns Hopkins University):* Dr. Simon Flexner has been appointed Professor of Pathological Anatomy.—*Budapest:* Dr. Ludwig Huttyasi has been recognised as *privat-docent* of Odontology, Dr. Karl Morelli as *privat-docent* of Laryngology, and Dr. Bernhard as *privat-docent* of Pathological Chemistry.—*Buenos Ayres:* Dr. Otto Voges, Assistant in the Berlin Institute for Infectious Diseases, has been offered the appointment of Professor of Hygiene and Director of the State Bacteriological Laboratory.—*Geneva:* Dr. de Marignac has been appointed Professor of Hygiene.—*Heidelberg:* Dr. C. Jung has been appointed Director of the Odontological Institute.—*Moscow:* Dr. A. V. Martinoff has been recognised as *privat-docent* of Surgery.—*Naples:* Dr. Maglieri has been recognised as *privat-docent* of Hygiene.—*Pavia:* Dr. F. Villa has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Turin:* Dr. Fusari of Modena has been appointed to the chair of Anatomy in succession to the late Dr. Giacomini.—*Vienna:* Dr. Philipp Knoll of the German University of Prague has been appointed to the chair of General and Experimental Pathology in succession to the late Professor von Stricker. Dr. Paltauf has been appointed Professor of General Pathology and Pathological Histology.

CARDIFF BOARD OF GUARDIANS.—At the meeting of the Cardiff Board of Guardians held on Dec. 10th a letter was received from Dr. J. J. Buist resigning his seat as a guardian. The chairman expressed his regret that Dr. Buist had found it necessary to leave the board.

DIPHTHERIA IN SWANSEA.—The medical officer of health of Swansea (Mr. E. Davies) has ordered all the schools in the borough of Swansea to be closed for the Christmas holidays a week earlier than was intended owing to the continued prevalence of diphtheria.

RAILWAY ACCIDENT TO A MEDICAL MAN.—On Dec. 15th Mr. A. Jeffreys, assistant to Dr. R. McGhie, of Abercanaid, Glamorganshire, by mistake got out of a train on the side opposite the platform at Abercynon Station, and falling on the line was run over by a mineral train, with the result that both arms were practically severed from the body. After receiving medical attention Mr. Jeffreys was conveyed to the Cardiff Infirmary.

CHARGE OF PERJURY AGAINST A SURGEON.—Mr. James Jerome Mackay, who was charged before Mr. Plowden at the South-Western police-court on Wednesday last with committing wilful and corrupt perjury at an inquest held by Mr. A. Braxton Hicks, coroner for the south-western district, on the body of a child named Ernest Mackenzie, was discharged, the magistrate remarking that in his opinion the case was simply one of difference of opinion among medical men and no assignment of perjury could be founded upon an expression of opinion.

DIPHTHERIA IN LONDON.—In the two periods, each of four weeks, ended respectively on Nov. 5th and Dec. 3rd, the amount of diphtheria in London was almost identical. Not so, however, either the deaths or the case-rate of mortality. In the earlier period all districts of London were invaded save one, but two escaped invasion in the later period. In the earlier there were seven districts each with 50 notifications and upwards, with an aggregate of 507, and other seven districts with only 10 in all; whilst in the later period eight districts had each upwards of 50 notifications and a total of 517, other six sanitary areas having only 17 in all amongst them. Despite these variations there was a difference of 3 only in the sum total of the notifications in London, the figures for the periods being 1087 and 1084 respectively, the latter yielding a weekly average of 271 cases. As regards deaths, the 145 deaths, with an average of 36 weekly, and a case-rate of 13·3 per cent. of the earlier period gave place to 156 deaths, or 39 weekly, and a case rate of 14·4 per cent. The minimum and maximum weekly deaths numbered 31 and 43, but the corrected decennial average for the corresponding weeks of the years 1888-97 was in no instance exceeded. The several weeks of this later period, in fact, yielded totals which respectively were 22, 5, 16, and 7 below the corrected average. In the outer circle, the 51 deaths in the early period gave place to 65 (11, 21, 16, and 17), of which 22 belonged to West Ham registration district.

MEDICAL MAGISTRATES. — Mr. Thomas S. Rowe, M.D. Edin., of Margate, has been appointed a magistrate for the Cinque Ports.—Mr. William Brown Holderness, M.R.C.S. Eng., L.S.A., of Windsor, has been appointed a magistrate for that borough.—Mr. Charles W. Wilson, M.B. Durh., M.R.C.S. Eng., has been appointed a magistrate for the borough of Bridport.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL. — At a special meeting of the governors held on Dec. 15th for the purpose of electing an honorary surgeon in the place of Dr. Charles Booth, resigned, Mr. R. T. Gratton who presided remarked that Dr. Booth had served in that capacity for thirty-five years, rendering during that period most valuable services to the welfare of the institution and it was satisfactory to know that they would still retain him as an honorary consulting surgeon. Dr. Booth had declined to accept any personal gift in token of their appreciation of his services but had consented to sit for his portrait in oils, which is to adorn the walls of the hospital board-room.

APOTHECARIES' HALL OF IRELAND. — At a meeting of the Governor and Court of the Apothecaries' Hall of Ireland the following gentlemen were appointed to conduct the examination in medicine, surgery, and midwifery for the year 1899:—Chemistry and Physics: Professor W. N. Hartley, F.R.S., and Mr. C. R. C. Tichborne. Pharmacy: Mr. W. V. Furlong and Mr. G. A. Stritch. Anatomy: Dr. J. Campbell and Mr. P. J. Fagan. Biology: Dr. F. Adye-Curran and Dr. J. A. Johns. Materia Medica: Mr. John Evans and Mr. S. M. Thompson. Physiology: Dr. C. M. O'Brien and Dr. G. B. White. Hygiene: Sir Charles Cameron and Dr. J. M. Day. Medical Jurisprudence: Mr. H. A. Auchinleck and Mr. J. E. Kenny. Pathology: Dr. J. Knott and Dr. C. M. O'Brien. Midwifery and Gynæcology: Dr. T. More Madden and Dr. R. D. Purefoy. Ophthalmology: Mr. F. Odevaine and Dr. R. J. Montgomery. Surgery (appointed by the General Medical Council): Mr. H. G. Howse and Dr. H. A. Thomson. Medicine: Dr. W. E. Ashley Cummins and Dr. M. McHugh.

PRESENTATIONS TO MEDICAL MEN.—Mr. Arthur Nathaniel Davis, L.R.C.P., L.R.C.S. Edin., the late medical superintendent of the Plymouth Borough Asylum, Blackadown, who will shortly enter upon his duties as medical superintendent of the Devon County Asylum, was last week entertained to dinner at the Royal Hotel, Plymouth, by his municipal colleagues, on whose behalf he was presented by the Town Clerk (Mr. I. H. Ellis) with a case of silver salt-cellars as a token of esteem.—Mr. W. J. Howarth, M.D., D.P.H. Vict., Medical Officer of Health for the borough of Bury, Lancashire, has been the recipient of a silver inkstand from the Bury sanitary inspectors.—On his retirement from office as honorary physician to the Bradford Royal Infirmary Dr. H. C. Major was recently entertained at dinner by the honorary medical and surgical staff and presented with an illuminated address and an album containing the photographs of the staff. Previously Dr. Major had been the recipient of an illuminated address from the board of management of the infirmary and of an aneroid barometer from the resident staff.

LEEDS SCHOOL OF MEDICINE.—The twentieth annual dinner of past and present students was held on Dec. 8th at Powolny's Restaurant. The chair was occupied by Dr. James Braithwaite, honorary obstetric physician to the Leeds General Infirmary, the vice-chairmen being Dr. J. Dobson and Mr. Edmund Robinson. A large number of the staff of the medical school and infirmary were present, including Mr. Littlewood, Mr. W. H. Brown, Dr. T. W. Griffith, Dr. E. F. Trevelyan, and Mr. Moynihan. About 100 gentlemen sat down to dinner. After the loyal toasts had been duly honoured Mr. Hugh Kee'ing proposed "The Staff" which was replied to by Dr. Braithwaite and Mr. E. Robinson. Mr. W. H. Brown, in the absence of Dr. Barrs, proposed "The Students, Past and Present," which was replied to by Dr. Dobson and Mr. Collinson. The toast of "The Visitors," proposed by Dr. Griffith, was replied to by Mr. Hutton on behalf of Owens College, Manchester, and by Mr. Ouranofski on behalf of University College, Liverpool. Selections of music were played during dinner and songs were contributed during the evening by students both past and present. A most successful evening was brought to a close by the singing of "Auld Lang Syne."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, E. W., F.R.C.S. Eng., L.R.C.P. Lond., M.R.C.S., D.P.H., has been re-appointed a Medical Officer by the Slough Urban District Council.

BLAKER, PERCY S., M.R.C.S., L.R.C.P. Lond., has been appointed a House Physician for the City of London Hospital for Diseases of the Chest, Victoria-park, E.

BURGESS, R., M.B., C.M. Aberd., has been appointed a certifying Factory Surgeon for the Stanley District, Perthshire, vice W. Peddie.

BURROW, VINCENT, M.B., B.S. Durh., M.R.C.S., L.R.C.P., has been appointed a Medical Officer for the No. 2 Sanitary District of the Aylesbury Union.

CRISP, A., M.R.C.S., has been re-appointed a District Medical Officer by the Smallburgh District Council.

EDMUNDS, F., L.R.C.P. Lond., M.R.C.S., has been appointed an honorary Surgeon for the Chesterfield and North Derbyshire Hospital, vice C. Booth, resigned.

FORSTER, J., M.B., C.M. Glasg., has been appointed a Medical Officer for the Conisbrough Sanitary District of the Doncaster Union.

GOSSAGE, A. M., M.B., B.Ch. Oxon., M.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Physician for the East London Hospital for Children and Dispensary for Women at Shadwell.

HALL, J. FIELD, M.B., M.Ch., has been appointed an Assistant Physician for the Hospital of St. Francis, New Kent-road, London.

HAMILTON, W. C., M.B., C.M. Edin., has been appointed a Certifying Factory Surgeon, Plymouth district, vice W. A. Buchan.

HAY, P. G., M.B., C.M. Aberd., has been re-appointed a Parochial Medical Officer by the Forgue Council.

HILLMAN, G. B., L.S.A., has been appointed a Medical Officer by the Castleford Urban Council, vice E. W. Kemp, resigned.

IRONSIDE, JAMES, M.B., C.M. Aberd., has been re-appointed a Medical Officer for the Parish of Laurencekirk.

JEPHCOTT, C., M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Physician for Guy's Hospital, London, E.C.

KELYNACK, T. N., M.D. Vict., Ch.B., M.R.C.P. Lond., has been re-appointed a Medical Officer for the Manchester Royal Infirmary.

KITCHIN, P. L. S. A., has been appointed a Medical Officer for the Box and Ditteridge Sanitary District of the Chippenham Union.

LAPTHORN, C. A., F.R.C.S. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed, *pro tem.*, Medical Officer for the Littlehampton district of the East Preston Union, vice F. C. Bryan, resigned.

LATHAM, A. C., M.A., M.B. Oxon., M.R.C.P., has been appointed Assistant Physician to St. George's Hospital, London.

LAWSON, F. H., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon for the Darlington Hospital and Dispensary.

MATHEW, G. PORTER, M.A., M.D., B.C. Cantab., M.R.C.S., L.R.C.P., has been appointed Assistant Surgeon for the Provincial Hospital, Port Elizabeth.

MAY, G. E., L.R.C.P. Lond., M.R.C.S., has been appointed a Medical Officer for the Third Sanitary District of the Ware Union.

MELLAND, CHARLES, H., M.B. Lond., M.R.C.S., has been appointed a Resident Medical Officer for the Manchester Royal Infirmary.

MITCHELL, A., M.B., C.M. Edin., has been re-appointed a Medical Officer for the Parish of Old Machar.

RAWES, WILLIAM, M.D., F.R.C.S., has been appointed Medical Superintendent for St. Luke's Hospital, London, E.C.

ROBERTSON, W., M.D. Glasg., D.P.H., has been appointed a Medical Officer and Police Surgeon for the city of Perth.

ROLLESTON, H. D., M.D. Cantab., F.R.C.P., has been appointed Physician to St. George's Hospital, London.

SMITH, S., M.R.C.S., has been appointed a Medical Officer for the West Malvern Sanitary District of the Ledbury Union.

STEVENSON, BRUCE, L.D.S., has been appointed a Clinical Dental Assistant for the Hospital of St. Francis, New Kent-road, London.

STONHAM, H. A., L.R.C.P., M.R.C.S., D.P.H., has been appointed Public Vaccinator for the Stepney Union.

STREETEN, F. E., L.R.C.P. Edin., M.R.C.S., D.P.H., has been re-appointed a Medical Officer by the Old Swindon Urban District Council.

TARGETT, J. H., M.B. Lond., B.S., F.R.C.S., has been appointed an Assistant Obstetric Surgeon for Guy's Hospital, London.

TAYLOR, HUGH, L.R.C.P. Edin., M.R.C.S., has been re-appointed a Medical Officer of Health by the Smallburgh Rural District Council.

TURNER, JOHN ANDREW, M.B., D.P.H., has been appointed County Medical Officer of Health for Hertfordshire.

WILLANS, W. B., L.R.C.P. Edin., M.R.C.S., has been re-appointed a Medical Officer by the Ware Board of Guardians.

Vacancies.

Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat Hospital (2 P.M. and 6 P.M.).

SATURDAY (31st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat Hospital (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

THE CUNEO GIANT.

"NATURE brings not back the mastodon," says Tennyson, and human giants since the semi-mythical days of Theseus who (according to Plutarch) did so much to destroy the breed do not tend to reproduce themselves; in fact, King Frederick the Great's father whose passion for colossal grenadiers Macaulay ridicules so effectively would find it hard to get together a company, much less a regiment, of recruits 7 ft. high. Year by year the armies of southern Europe especially experience greater difficulty in reinforcing the line with youths of the proper stature and thoracic girth, and in Italy the "gracilità

Digitized by Google

crescente" (increasing slenderness) seems, according to her military authorities, coincident with an unexpected loss of height. In these circumstances the appearance of a veritable giant in the subalpine town of Cuneo is a phenomenon deserving of more than vulgar curiosity. This overgrown individual is a native of the Piedmontese hamlet of Vinadio where he was born twenty-two years ago. His altitude is (in metres) 2·25, his thoracic circumference is 1·60, and his feet are 45 centimetres long. He had to return from France the other day to present himself to the military authorities of this district who, finding it difficult to enrol him in the levy, keep him under observation at the hospital of Savigliano. His slow elephantine movements seemed to unfit him for active service; not a bed in the barracks was big enough for him; if he had to mount guard no sentry-box, in the event of a shower, could admit him. His railway journeys had to be performed in a cattle-truck, and he had to be brought round to the train by an entrance outside the station which had no wicket wide enough to let him through. What the poor fellow's occupation in life is to be is a grave problem to his relatives and friends. Mobbed wherever he appears in public he will be constrained to keep in doors—possibly to earn his livelihood by receiving visitors at so much a head. It will be as respectable a "profession" as that of his compatriot Succi, the fasting-man, who makes his bread by refusing to eat it!

WHAT IS LEGITIMATE ENTERPRISE AND WHAT IS "STEALING A MARCH"?

To the Editors of THE LANCET.

SIRS,—I wish to ask your views on a subject of some importance to myself. I live in a small town just outside what may be called the suburbs of London. In one direction the town has spread to a railway station beyond which lies a village. Here recent building has taken place so that the village and the town form practically one residential neighbourhood. At the junction lives a medical man concerning whose attitude towards me I am seeking advice. I have patients in the village and this spring I hired rooms from a chemist residing there and made arrangements to attend my patients at these rooms on certain days at certain hours to their obvious convenience and mine. One day I received a letter from the medical man who lives at the junction saying that he had "ascertained out of curiosity the opinion of the *British Medical Journal* on my recent step" and to my great surprise I found my conduct pilloried in that journal as "savouring strongly of touting, advertising, and stealing a march on a professional brother." Knowing that I had been guilty of none of these things I wrote for a copy of the letter which had betrayed the editor of the *British Medical Journal* into such vilification of me. On this being supplied to me I at once found that the *British Medical Journal* had been inaccurately briefed. I wrote to the *British Medical Journal* repudiating the conclusions that had been drawn and that paper with great courtesy said, "We willingly give publicity to this repudiation and take the opportunity of stating that our reply was not intended to have any individual application." In spite of this I am informed that a use has been made of the first opinion of the *British Medical Journal*—a use designed to prejudice me in the eyes of the medical profession and in my business connexions. Will you kindly advise me what steps, if any, I should take? The consulting-room in the village was started entirely for the convenience of patients who were already my patients. It was in no sense a branch practice, for it was not worked by an assistant but by myself as a *bonâ fide* development of my practice. I may add that the unfriendly action of my "professional brother" has done me no harm, but I naturally desire to stop further misrepresentation of my conduct.

If you would like the letters and newspaper cuttings respecting the whole matter I shall be pleased to let you have them.

I am, Sirs, yours faithfully,

Dec. 12th, 1898. E. J. D. M.

*** We have received the letters and newspaper cuttings. The *British Medical Journal* has expressly repudiated any intention of applying to "E. J. D. M.'s" individual conduct the offensive criticisms in question. To make use, therefore, of the earlier note, written before "E. J. D. M.'s" explanation reached our contemporary, is to commit the exact offence which the *British Medical Journal* has pilloried—it is "to steal a march on a professional brother" by representing him wrongly as a tout and an advertiser. We are asked by "E. J. D. M." to advise him about any steps he should take. As he admits that he has suffered no harm in his practice we advise him to take no steps at all.—ED. L.

MEDICAL JOURNALISM IN MARYLAND.

AT the semi-annual meeting of the Medical and Chirurgical Faculty of Maryland held at Frederick on Nov. 16th, 1898, Dr. Horace M. Simmons of Baltimore, manager of the *Maryland Medical Journal*, read a paper entitled "Medical Journalism in Maryland." Medical journalism in that State dates, he said, from the month of April, 1808, when Dr. Tobias Watkins established in Baltimore the third medical journal edited and published in the United States. It was called the *Baltimore Medical and Surgical Recorder*. The founder is said to have been a man of ability and culture. His journal was announced as a quarterly and the first number contained eighty pages of printed matter, embracing original papers, extracts, selections, miscellany, reviews, and correspondence. It was ably conducted, but the editor acknowledged in the preface to his second year's volume that he had been disappointed of the coöperation and patronage which he expected and the paper came to an end in 1809. A period of two years then elapsed, at the end of which the *Baltimore Medical and Philosophical Lycaeum* made its appearance under the direction of Dr. Nathaniel Potter, professor in the College of Medicine of Maryland. It was published quarterly at $2 per annum, but was discontinued after the fourth number. Following the suspension of the *Lycaeum* there was an interval of eleven years, when the *Baltimore Philosophical Journal and Review* appeared under the editorship of Dr. John B. Davidge, professor of anatomy in the University of Maryland. It contained 200 pages of well-arranged original and selected matter, but did not get beyond the initial number. The next venture was the *Maryland Medical Recorder* which was established in 1829 by Dr. Horatio G. Jameson, professor of surgery in the Washington Medical College. It only reached the third volume. In February, 1830, prior to the suspension of the *Recorder*, a rival periodical appeared under the name of the *Baltimore Monthly Journal*, edited by Dr. Nathan R. Smith, professor of surgery in the University of Maryland. The subscription price of this monthly was $3 per year if paid in advance or $4 if paid at the end of the year. Dr. Smith contributed most of the matter to the journal and was assisted in his editorial duties by an association of physicians and surgeons. This venture did not long survive. In the year 1833 another association of physicians and surgeons, in coöperation with Dr. E. Geddings, professor of anatomy and physiology in the University of Maryland, established the *Baltimore Medical and Surgical Journal and Review*, published semi-annually. The suspension of the *Review* in 1834 occasioned so much regret on the part of the profession that the editor concluded to resume publication under the monthly form and with the name of the *North American Archives of Medical and Surgical Sciences*, but this renewed effort was terminated after one year's experience. Under the auspices of the Medical and Chirurgical Faculty of Maryland an official organ of the Medical Department of the United States army and navy was started in 1839 as the *Maryland Medical and Surgical Journal*. It was at first edited by a committee of six, but subsequently by Dr. G. C. M. Roberts and Dr. Samuel Chew. The journal was a marked improvement over all previous attempts, but in March, 1843, it ceased to exist. Maryland was now left without a professional journal for a period of seventeen years when, in January, 1860, the *Virginia Medical Monthly* changed its name to the *Maryland and Virginia Medical Monthly* and entered upon a new series. The office of publication was in Richmond. The troubles growing out of the civil war caused the early suspension of the journal. In January, 1861, Dr. Edward Warren, professor of materia medica and therapeutics in the University of Maryland, established the *Baltimore Journal of Medicine*. In consequence of the civil war Dr. Warren gave up the publication and went home to the south, but after the war he returned to Baltimore and established the *Medical Bulletin*, a semi-monthly journal of medicine and surgery. In 1870 this periodical having reached volume ii. was united with the *Baltimore Medical Journal* under the name of the *Baltimore Medical Journal and Bulletin*. The *Baltimore Medical Journal* had been started the same year by Dr. E. Lloyd Howard and Dr. T. S. Latimer. No. 10 of volume ii. was the last of the consolidated publications to appear. The College of Physicians and Surgeons in 1872 began the publication of the *Physician and Surgeon* which was afterwards changed to the *Baltimore Physician and Surgeon*. Volume vi., No. 5, marked the date of its demise. In May, 1877, the *Maryland Medical Journal* was brought out under the editorial and business direction of Dr. H. E. T. Manning and Dr. T. A. Ashby. Originally a monthly it was changed to a semi-monthly in May, 1880, and to a weekly when it reached volume x. The property was purchased in 1894 from Mr. William R. Ashby by the present owners who constitute an incorporated company. Since the date of the founding of this journal there have appeared and disappeared the *Independent Practitioner*, the *Baltimore Medical and Surgical Record*, and the *Medical Chronicle*. Dr. Simmons's paper is printed in the *Maryland Medical Journal* for Dec. 3rd, 1898, where it forms the opening article.

THE EXCRETION OF HIPPURIC ACID IN THE URINE.

IN the *Gazzetta degli Ospedali* of Dec. 4th Dr. A. Sertoli describes observations which he has made on the effect of disease of the kidney in the excretion of hippuric acid. For the estimation of hippuric acid in the urine he prefers Völcker's process which, although it requires considerable time, has the advantage of comparative accuracy. A sample of the twenty-four hours' urine measuring from 200 c.c. to 300 c.c. is evaporated to one-third in the water-bath, then mixed with 4 grammes of sodium phosphate and evaporated to a syrupy consistence, after which dry calcium sulphate is added and the whole well dried at from 80° to 90° C. The residue is then extracted with from 50 c.c. to 60 c.c. petroleum ether in a Soxhlet apparatus, the receiver of which is kept at 70° C. so that a continuous supply of condensed ether may pass through the percolator. In four or five hours the phenol, benzoic acid, and fatty acids are removed, after which the hippuric acid is extracted by percolating similarly with sulphuric ether for a period of from six to ten hours, and after crystallisation from the ether can either be weighed or estimated with decinormal caustic soda. Observations made on himself and continued for six days showed that his maximum ordinary excretion of hippuric acid was 0·88 gramme daily and the minimum 0·35 gramme, the average being 0·64 gramme. He then took increasing quantities of

Digitized by Google

benzoic acid on each of five consecutive days, at the same time estimating the hippuric acid excreted. The results were as follows:—First day: benzoic acid taken, 1 gramme; hippuric acid in urine, 0·88 gramme. Second day: benzoic acid taken, 2 grammes; hippuric acid in urine, 2·22 grammes. Third day: benzoic acid taken, 3 grammes; hippuric acid in urine, 2·91 grammes. Fourth day: benzoic acid taken, 4 grammes; hippuric acid in urine, 3·75 grammes. Fifth day: benzoic acid taken, 5 grammes; hippuric acid in urine, 4·51 grammes. Dr. Sertoli then made analogous experiments with 3 cases of chronic parenchymatous nephritis, 2 of chronic interstitial nephritis, and 1 of pyelitis, and he came to the conclusion that the elimination of hippuric acid is not affected to any important extent by the pathological condition. He is therefore of opinion that in the human subject the kidney is not the organ primarily concerned in the formation of hippuric acid.

PROFESSIONAL CONFIDENCE.

To the Editors of THE LANCET.

SIRS,—I should feel much obliged by your inserting in your next issue a reply to the following questions. What should I do under the circumstances I am about to relate? A is a patient of mine and B is his agent, in whose office is C as a clerk. D is a bailiff employed by A. B and D are also patients of mine but C is not. C writes me a letter marked on the outside *Private* and on the inside *Confidential* saying "B was pressed for time so asked me to write you as to what you thought about D's case and what the upshot would be," signing it in his own name only. Am I justified in giving C or even B this information? Thanking you in anticipation,

I am, Sirs, yours faithfully,

Dec. 13th, 1898. X.

*** Of course our correspondent must respect D's confidence entirely. He must say nothing to B, C, or any other person concerning D's health which he has gathered in a professional way without D's express permission, and he will be wise, if that can be obtained, to have it in writing.—ED. L.

THE UNQUALIFIED PRACTITIONER AGAIN.

AN inquest was held recently at Wrexham upon the body of a child, aged five years, who died on the way to the Wrexham Infirmary from the results of burns. The child was burned some days before her death and was attended until the day of death by a man named William Henry Howard, a contractor at the Brymbo-street works. At the inquest Howard is reported as saying that he had attended thousands of burning cases and thought himself as good at the job as any medical man in North Wales. The coroner warned him that he might one day find himself committed for manslaughter, to which Howard replied, "If a doctor sends for me I cannot refuse to attend." The coroner, "You seem to me to be a mass of conceit. You are running a very grave risk indeed in attending these cases up and down the country and charging half-a-crown a visit." The inquiry was adjourned for the attendance of the infirmary surgeon.

"LUNATICK ASYLUMS."

WE have received a small pamphlet bearing the above title. The sub-title is "An Essay by a Doctor of Arts, Oxford." The degree is one we are not familiar with, and if conferred by any university it is certainly not so by the University of Oxford as would seem to be implied. The writer's argument would seem to be shortly that (1) asylums are too palatial and luxurious; (2) that weak-minded persons should be treated in separate establishments, however small and homely; (3) that there should be no private madhouses; (4) that asylums are conducted on the lines made familiar to us by such works as "Valentine Vox" and "Hard Cash"; and (5) that "into these establishments the young and unfortunate are trepanned—magisterial warrants not even solicited— ....." That the "overwrought" should be tended in a home something resembling the best kind of almshouse is an idea with which we can all agree, but that the modern lunatic asylum is anything like the institution which a "Doctor of Arts" describes or that Lunacy Commissioners neglect their duty, as he implies, is absurd.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—A curious error appears to have crept into the report of Koch's lecture given in THE LANCET of July 2nd. It is there stated that "the mosquitoes probably deposit their eggs on the human body, the parasites issue from these eggs and when their number has increased the disease develops." Koch's suggestion is otherwise. It is that the parasite is passed on through the eggs and larvæ to the imago which is the active agent for disseminating the disease. The exact words, taken from the authorised translation of the lecture, are: "The mosquito receives the parasites, transmits them to its eggs and the young larvæ, and only the next generation is able again to infect with malarial parasites. Nor does it seem to me impossible that the parasites maintain themselves in the mosquitoes through several generations."

I am, Sirs, yours faithfully,

Dec. 20th, 1898. C. H. E.

THE "CALTON" STYLOGRAPHIC PEN.

ONE of these pens has been sent to us for use and has given every satisfaction. We have found it simple in working and easy to write with. It is supplied by the Jewel Pen Company, 58, Fenchurch-street, E.C.

THE "INSTRA WARMER."

WE have received from Messrs. Blair and Co., of 47, Cannon-street, E.C., one of their Instra Warmers which was referred to under the title of the "Sun Pocket Stove" in THE LANCET of Nov. 28th, 1896. There is apparently no difference in the construction of the "Warmer" now before us and the one which we previously noticed. No doubt in many cases, especially in travelling, this handy little contrivance, easily carried in any pocket, being about 4½ in. by 2 in. by 1⅛ in., would be a boon on cold days; and to those who are constitutionally troubled with cold hands it appears to provide a solution of the difficulty experienced in meeting their requirements. The heat is obtained by the slow combustion of a carbon rod placed inside a metal case and each rod lasts for about four hours.

THE "LIBERATOR" FUND.

EVERYONE will remember Thackeray's masterly description of the arch-swindler Brough in the "Great Hoggarty Diamond" and how the fall of the Great Diddlesex Association brought misery upon thousands of small shareholders. The Liberator *fiasco* was upon exactly the same lines even to the unctuous piety and scoundrelism of the chief actors. It will be remembered that a fund was got up for the relief of the sufferers by the collapse of Jabez Balfour. Although £82,000 have been distributed some £18,000 are still required. In the appeal issued by Mr. Stockwell Watts it is sad to see the smallness of the amounts lost for it shows the humble circumstances of most of the victims. Hardly anyone seems to have lost more than £500. It is a truism to say that Christmas is above all others the season for charity, but the Liberator Fund is a most worthy one to help and those who can spare anything towards it may feel assured that their moneys will be only distributed to the really deserving.

A COMMON AILMENT.

A SANITARY engineer living in a Kentish village not far from London sends us the following amusing description of local feeling in the district concerning their water-supply: "Our village water-supply—the spoilt child of our parish council—is suffering from a very common ailment—*neglect*—which may develop into a serious attack of typhoid or other preventable disease. Its grandmother and mother ('Spiritual Scientists'), its godmothers and its aunts ('Peculiar People'), are terribly indignant to think that their only child should be taken from them and placed under the charge of the rural district council just because they refused to apply the simple common-sense remedies prescribed by the medical officer of health. Public sympathy is requested."

R. L. S.—We never recommend individual practitioners. Our correspondent must consult his own medical man.

Ignarus.—There is no breach of etiquette in the proposed addition under the circumstances described.

Mr. L. Weiss.—We do not recommend individual practitioners, whether specialists or not.

Colonial will find full information in the current Medical Directory p. 20.

ABSTRACT OF

The Morison Lectures

ON

THE RELATION OF THE NERVOUS SYSTEM TO DISEASE AND DISORDER IN THE VISCERA.

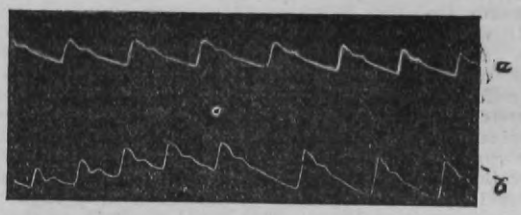
Delivered before the Royal College of Physicians of Edinburgh on Nov. 7th, 9th, and 11th, 1898,

BY ALEXANDER MORISON, M.D., F.R.C.P. EDIN.,

PHYSICIAN TO OUT-PATIENTS AT THE GREAT NORTHERN CENTRAL HOSPITAL AND CHILDREN'S HOSPITAL, PADDINGTON-GREEN.

LECTURE III.[1]

Delivered on Nov. 11th.



DISORDERS OF VISCERAL MOTION.

SIR JOHN TUKE AND FELLOWS,—The separation of sensation from motion is relatively to the mind a distinction in what may be termed objective consciousness. We feel pain and can localise it and we can observe movement. The separation of sensibility from motility is a finer distinction and is largely in what we may term subjective consciousness or reasoning. Essentially the transmutation of one form of motion into another merely emphasises the common property by which a living universe is conditioned. Clinically the distinction is convenient and no circumstance reveals more instructively the relation of the nervous system to visceral motion than the influence one organ has upon another. The displaced or twisted kidney which induces a tachycardia, the diminished thyroid secretion which causes a cardiac stagger or a bradycardia, the retained excretion or the peripheral excitation which induces a convulsion, or the functional inactivity generally which disturbs metabolism,—all show how intimately one form of motion is related to another; and when we emphasise motility in a given clinical condition we might rationally regard it in some instances as the motor feature of an essentially sensory and causal disorder. In touching upon some points illustrative of the relation of the nervous system to viscero-motor disease and disorder I shall follow the plan already adopted in discussing sensory disorders and take as the type of disordered visceral motion abnormalities in the action of the heart, making reference incidentally to analogous conditions in other organs.

The motor innervation of the heart we know is accelerant and augmentor-motor, inhibitory and depressor-motor, and trophic or pneumogastric proper, all these movements having necessarily their sensory concomitants or equivalents. Gaskell and his successors, anatomical and physiological, have revolutionised, as we learned last year, our conceptions of the visceral nervous outflow in general, including the innervation of the heart. For whereas we formerly regarded the pneumogastric as a primary and the cervical sympathetic as a secondary source of cardio-motor innervation, we now believe that the pneumogastric is a secondary and the cervical sympathetic a tertiary source of such innervation. Whether all the supra-thoracic vaso-motor outflow originates as low down as the second dorsal spinal nerve appears still to be somewhat doubtful. Hill and Bayliss[2] failed to evoke vaso-motor action in the intracranial circulation by electrical stimulation from this region. Without the aid of experimental physiology and merely using the microscope for anatomical research I have met with conditions bearing on this point which will be seen on the table and are reproduced on the screen. It will be seen that what appear to be the sources both of the pia matral and pia vascular innervation are certain tassel-shaped bodies which are arranged centripetally to the vessels and of which I give a short account this month (November) in the *Edinburgh Medical Journal*. The precise locality of these vessels I have not yet had an opportunity of determining, but they appear to me to be sufficiently characteristic in design to be capable of identification by injected specimens. Thus identified, the position of the bodies in question, whether they be the source of vaso-motor nerves or no, should also be determinable.[3] In the meantime we may assume, notwithstanding Hill's and Bayliss's failure to elicit response, that the outflow of the indubitably existent vaso-motor nerves in the pia mater is from the same region as the general vaso-motor outflow, that is, below the level of the first dorsal nerve, and thus bring the vaso-motor phenomena of all the viscera including the brain, into line.

Cardiac motion, like secretory and other motion, may be average or normal and plus or minus. A mid-point or equilibrium is a balance of extremes and vital equilibrium is maintained by a certain variation around a centre of equipoise. Acceleration and retardation, augmentation and depression, constantly correct one another with the sensitiveness of a species of tentacula to surrounding circumstances, these tentacles being the nerves and the properties with which they are endowed. This is well exemplified by the influence of respiration on the character and rate of the radial pulsation. (Fig. 1.) The sphygmogram I throw on

FIG. 1.

a, Pulse during quiet respiration. *b*, Pulse during forced respiration.

the screen shows the small waves of forced inspiration on the ascending portion of the curve, followed by the large waves of prolonged expiration on the descending portion. These are no more the evidences of a mere pneumatic suction and propulsion than the cerebral circulation is the passive arterio-venous balance which Monro and his disciples conceived it to be. The pneumatic conditions play a part in the one as the comparative resistance to atmospheric pressure does in the other, but the character and rate of the waves in the two portions of the curve indicate a vaso-motor regulation, the peripheral incentive to which is, I believe, to be found in the increased pressure in the dextral chambers of the heart and pulmonary circuit during inspiration. For comparison with the tracing of forced respiration I show one of the pulse of the same subject taken at the same time during quiet breathing in which the pneumatic factor is conspicuous by its absence, although in a minor degree doubtless still operative. (Fig. 1*a*.)

The antagonistic action of the accelerant and retardant nerves of the heart has been disputed. Retardation can be induced when artificial acceleration is in progress. It is none the less true that the safety of an abnormally inhibited heart consists in some acceleration of cardiac pulsation and, as was mentioned last year, in the sphere of secretory motion there appears to be a certain compensatory independence in the secretory influence of the cranial and sympathetic nerves of the submaxillary gland. It is probable that the same rule applies to other forms of vital motion. Dr. William Hunter,[4] referring to the fact that intense and even fatal jaundice may rapidly follow emotional shock, accounts for the phenomenon by suggesting a spasm or reversed peristalsis of the bile-ducts while the bile is in full flood as the probable cause. He admits, however (p. 81), that diminished quantity and increased viscidity of bile may be a cause of its absorption. The viscidity he attributes to catarrh of the bile-ducts. Can a more directly neurotic hypothesis be advanced?

The main secretory nerve of the liver is the pneumogastric and its sympathetic endowment is from the splanchnic nerve, while vaso-motor nerves for the portal vein are derived (according to Bayliss and Starling, quoted by Haliburton[5]) from nerves ranging from the third to the

[1] Lectures I. and II. were published in THE LANCET of Dec. 17th and 24th, 1898, respectively.

[2] Journal of Physiology, 1895.

[3] The neural nature of these structures has been disputed by a good microscopist, but I believe I am correct in maintaining the view I have expressed.

[4] Allbutt's System of Medicine, vol. iv., p. 68, et seq.

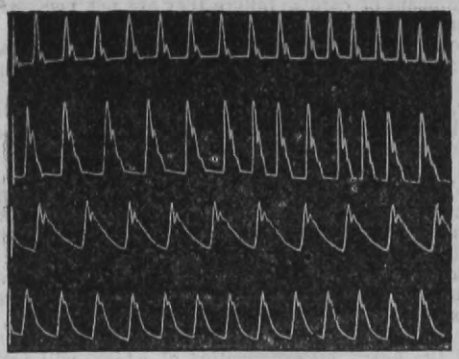
[5] Op. cit., p. 670.

Digitized by Google

eleventh dorsal. It appears possible, therefore, that the sequence of events may be somewhat as follows: in sudden, severe, and mental cases shock is followed by pneumogastric inhibition and arrest of its secretory-motor function. This entails an attempt on the part of the sympathetic to come to the rescue which it does by producing a more potent but also a more viscid bile, the nature of such potency not being at present to the point, which, like a blundering but well-meaning friend, stands in the way just when the pneumogastric having recovered from its inhibition throws out by augmented activity too large an amount of bile for rapid escape, hence absorption and rapid toxæmia in some cases and slow poisoning in others. I do not for a moment presume to indicate this solution as correct, but it appears to me to be as probable as other theories suggested and brings the motor activities of the liver into line with those of the heart, which is my present purpose. Again, the striking phenomena on the one hand of Graves's disease, which I prefer on this occasion to call Begbie's disease, and on the other of myxœdema appear to suggest a parallel on similar lines. The thyroid gland is innervated by the pneumogastric and by visceral nerves which reach it by way of the inferior and middle ganglia of the cervical sympathetic. Of these its most active secretory nerve is probably the pneumogastric, although I am not aware that the fact has been experimentally proved. If we regard Begbie's disease as in the first instance a cardio-vascular neurosis, to employ a term expressive of our ignorance, we can conceive an increased though ineffectual effort upon the part of the pneumogastric system—that is, of motor fibres probably derived from the spinal accessory nerve and coursing in the pneumogastric—to restrain the cardio-vascular organs in excessive visceral motion, and although unsuccessful in that effort so stimulated by it as to provoke increased activity in its own secretory motor fibres. This would result in an excessive secretion among others of the thyroid juice, the effect of which upon the circulation is to accelerate it. Thus the increased activity of that gland may add fuel to the fire which burns so lustily as vaso-motor commotion in the circumstances in question. This secretory increase, as we know, is at present regarded as one of the most probable causes of excessive pulsation in Begbie's disease, the etiology of which, however, is not yet by any means clear. It is conceivable, moreover, that a period of persistent hypersecretion may result in one of hyposecretion, the retardant influence of which may be slow in showing itself for the following reason: the sympathetic system, besides its general vaso-motor over-action, may also induce a supplementary sympathetic juice as in the case of the submaxillary gland and thus maintain for a time the waning accelerant influence of pneumogastric secretion. We know, however, that ultimately in a large number of cases the excessive excitement of the cardio-vascular system subsides more or less, that in some cases bradycardia succeeds tachycardia and that in yet others myxœdema takes the place of Begbie's disease. The neuro-motor activity of the gland, in short, and its associated organs is worn out and we may expect some day to have demonstrable pathological changes in the controlling centres which together with peripheral degeneration would account satisfactorily for the striking complex of symptoms. Action and supplementary action, endeavour and support, over-action and reaction, error and correction, seem to be general laws of life, and there does not seem to be any just reason why they should not apply also to the life manifest in visceral motion in its various form.

To study the matter a little more closely, and taking cardiac action as the type, let us examine the motor effects of shock upon the heart, and in the first instance of the shock of physical pain, with which Laycock's "phrenalgia" must necessarily be associated and often is in a high degree. As has already been remarked in a previous section, pain or excessive sensibility in any organ may influence the heart's action in association with various degrees of concomitant mental emotion proportionate to the amount of the stimulus. The tachycardia associated with displaced kidney may be present without much associated pain and therefore without great mental distress. With more pain the same conditions will be emphasised. The reflex effects of nephroptosis may affect many organs besides the heart and the severity of these secondary motor disturbances is not proportionate, as MacAlister has stated, to the amount of mere displacement.[6] Calculi, we have seen, may induce an extreme of agony which may terminate in collapse and death, the associated cardio-vascular phenomena being those of rapid and enfeebled action of the heart and a general vaso-paresis accompanied by profuse perspiration and depression of temperature. These extreme phenomena differ from those associated with angina pectoris chiefly in the situation of referred pain and in the uninterrupted duration of the agony. With this distinction these might be termed cases of angina pectoris hepatica, renalis, et hæc species omnes.

The first effect of sudden visceral pain, whether cardiac or general, on the movement of the heart is to arrest its action and probably could we at the moment of the onset of pain auscultate that organ we should detect an inhibition. This, however, like peripheral spasm, which is usually regarded as the cause of angina pectoris, is so early a phenomenon that it must very rarely be indubitably observed and when observed and present it is not necessarily the essential cause of the general complex of symptoms. The conditions usually first observed by the ear and the hand are the phenomena of depression which follow inhibition, associated in many cases shortly afterwards with those of a rescuing augmentation and acceleration of the heart's beat. Dr. Lauder Brunton was the first, so far as I know, to note graphically the cardio-vascular movements connected with valvular angina. In the Transactions of the Clinical Society of London (vol. iii.) he published a case of aortic valvular disease with sphygmograms in which he showed the quick small pulse of the agony and the larger and slower pulse of the interval free from pain. I throw on the screen a slide prepared from the published tracings. Dr. Brunton considered the pulse of the agony to indicate peripheral spasm and was at a loss to reconcile its rate with its assumed condition. Since Brunton's original observations, however, opinion has modified a good deal on this point and there are those who feel more disposed to regard the peripheral signs usually observed as those of empty collapse rather than of active spasm—of profound collapse in other words such as might be caused by other visceral and even somatic pain of a certain degree of severity. Sir Richard Douglas Powell, however, in his recent Lumleian Lectures before the Royal College of Physicians of London,[7] also describing what he terms vaso-motor angina in the case of a young man suffering from aortic regurgitation, spoke as follows: "It was curious to note the absolute extinction of all the aortic characters in the pulse which became contracted to a small, hard, pulsating thread, whilst as the patient sat forward leaning against a chair in great pain the bed shook with the violence of the cardiac beats and his neck and subclavian vessels could be seen pulsating with responsive violence. A dose of trinitrine quickly brought back the aortic features of the pulse and dissolved the painful scene. One could not observe the labouring beat of the heart—the strongly pulsating large vessels contrasted with the almost effaced small vessels—without appreciating the power of vaso-motor contraction to cause cramp or paralysis of a healthy ventricle; yet there are physicians who still doubt the efficacy of vaso-motor spasm in the mechanism of angina."



I presume it is because of the humane desire not to disturb unnecessarily the patient in the throes of cardiac agony that we find more frequent record of the condition of the radial pulse in these cases than of the heart itself. If, however, the heart of such a patient be examined it will be found that the extinction of "aortic character" which Sir Richard Powell noted in the radial pulse is also very distinctly appreciable at the aortic orifice itself. The usually very considerably hypertrophied left ventricle will be found to pulsate with increased frequency, the bruits significant of the valvular defect being almost or quite hushed, and increased tension in the pulmonary circuit indicated by a well-marked accentuation of the second sound at the pulmonary arterial orifice. There is repletion of the ventricular cavity and comparative emptiness of the extra-cardiac systemic arteries. The full and hypertrophied heart labours violently to rid itself of the residual stimulating and dilative burden of blood, not because it cannot jerk some of its contents into the larger comparatively empty vessels with more than "aortic" emphasis, but because its own intrinsic and momentary failure has cast upon it a paralysing weight which must be rapidly reduced if the organ is not to come to

Digitized by Google

a standstill. The small peripheral pulse which is associated with such valvular angina during the period of cardiac failure is not on this showing one of spastic narrowing but of empty collapse. The following sphygmograms which I published to illustrate a paper on the blood-pressure in angina pectoris in the Edinburgh Hospital Reports for 1895 may render my meaning clearer. (Fig. 2). The first shows the attack at

FIG. 2.

a, During angina at its height. *b*, Pain subsiding. *c*, Pain gone. *d*, Sphygmogram from the same case during a period of comparative compensation.

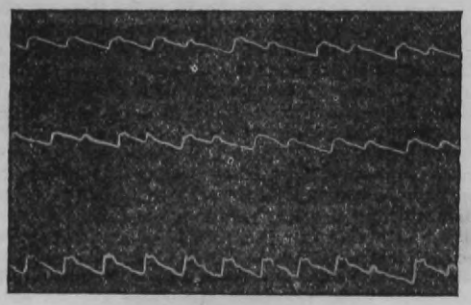
its height with a lowering of the predicrotic wave and a flat drag in the diastolic interval, meaning, as I think, that the collapsed and comparatively empty artery had failed to reach the lever of the instrument. In the next the cardiac force is increasing, its action becoming slower, and although blood still fails to reach the periphery in normal abundance there is a rise in the position of the predicrotic wave and an indication of dicrotism. Pain is still present under these circumstances but the patient is easier. The next sphygmogram represents the refilled and retarded pulse and the cessation of pain. The fourth and last tracing shows the typical aortic regurgitant pulse of the patient during a period of temporarily re-established compensation.

The conditions are somewhat different in the angina of arterio-sclerosis without valvular disease and also in those mainly associated with fatty degeneration of the heart. In the former, while the initial conditions of the attack are to my mind indubitably central, not peripheral, there may at times be noted a short period of simultaneous arterial hardening in association with a quickly pulsating heart. How much of this is spasm and how much the induration of an arterio-sclerotic and imperfectly filled vessel I have not been able so far to convince myself. The angina of the fatty heart, again, may be associated with a slow, full, and soft pulse without suspicion of spasticity, the irresponsive and degenerated ventricle throwing its contents into the systemic arteries with bradycardial sluggishness and in imminent danger of that syncope which so frequently overtakes it.

It has been mentioned that shocks which so markedly affect cardio-vascular movement may likewise influence secretory motion and I have suggested the presence of a supplementary or balancing secretion in such cases. Shock to the liver may, indeed, prove fatal to hepatic motion as shock to the heart may to cardiac motion, but it is probable for the reasons stated that minor degrees of shock may have their consequences averted by a supplementary mechanism in such a way as would not be possible but for that double innervation which is a fact in the anatomy of the viscera and but for that bilateral and double innervation which appears to play an important part in the innervation of unified or single viscera such as the liver and heart. This bilateral action is probably secured by an incomplete peripheral and plexal decussation which has not yet been demonstrated anatomically but of which there is good experimental evidence. Thus, as has been stated, section of one pneumogastric nerve has little effect upon cardiac motion, while section of both nerves permanently disables it, just as a similar lesion abolishes the glycogenic function of the liver.[8]

In addition to the transient phenomena of disturbed or excited but not necessarily disordered cardiac action to which I have referred in connexion with angina pectoris, changes of cardiac rhythm of a more persistent character may be met with, and on the nervous relations of these, taken as a type of viscero-motor irregularity in general, I desire to comment very briefly. I trust enough has been said to justify the thesis that in the regulation and maintenance of sustained visceral motion the nervous system always plays an important part. Its regulating faculty is more generally conceded, however, than its sustaining power. I assume, therefore, for the reasons stated, that in this respect also it plays essentially as important a part as the blood and the inherent irritability of the cell manifesting any particular form of motion. As I have stated the functional unit is not one but triune in every form of visceral motion, mobile, secretory, metabolic, and excretory, and that, differ as these may from one another in details of manifestation, they are subject to essentially the same order or regularity of action and to the same disorder or irregularity of action as the more objectively mobile form which we associate most readily with muscular tissue. With this perhaps unnecessary reiteration I proceed to say a few words concerning abnormal variations in cardiac action and their relation to the nervous system, regarding such as typical of other forms of disordered visceral motion.

The heart's action, undisturbed by forced respiration, bodily exertion, or mental emotion is, normally, quite regular. The eviscerated heart of an animal recently killed is also usually quite regular. Auricular systole precedes ventricular systole with automatic precision. Circumstances, in other words, which induce variation in stimulation are removed and rhythmical cellular action, one of the factors in the triune partnership, for a short period, alone or assisted by some residual storage of nervous energy or some remnant of stimulation by blood, continues to act with the unvarying rhythm which blood, nerve, and muscle in common contribute towards during life, when the persistently isochronic and isodynamic organ is undisturbed by extraneous stimulation. The first observable departure from this isochronia and isodynamia is a variation in rate rather than in force. The heart-beats are all complete in themselves and if when more rapid they are individually less powerful than a single slower beat, they collectively carry on the circulation with much the same efficiency as when the heart's action is more regular, provided no call is made upon the heart for additional exertion. This condition, when not due to mental excitement, as it may be (in which case it may be characterised either by augmentation or by depression or by both these states alternately) is usually due to variation in the stimulation of the cardio-vascular nervous system caused by variation in the tone of the chambers of the heart and in the amount of their contents. This simplest form of abnormality may be termed "anisochronia" as variation in rate is more easily appreciable than variation in power. If the condition be present for any length of time the variation in force becomes more noticeable and to irregularity in rate is added irregularity in the size of the pulse wave. The systole may have half its normal force or less than half—a condition which may in general terms be called "hyposystole." (Fig. 4 *b*.) Now, inasmuch as the empty and eviscerated heart may have a perfectly regular rate and amount of systole this hyposystolic condition cannot be attributed to the amount of blood in the chambers of the heart. It must, therefore, be due either to the muscular or neural factor. The muscular factor, we have seen, with the nervous and hæmic factor at a minimum may act perfectly regularly and irregular post-mortem tremor of muscular tissue is most frequently observed in somatic, not visceral, muscle. On the other hand, there is abundant evidence—clinical, physiological, and pharmaceutical—to prove that stimulation of the nervous system may profoundly influence the action of visceral muscle in augmenting or depressing it and in hastening or retarding it. It seems, therefore, rational to conclude that variations in cardiac action during life, whatever the special character of the rhythm, must be largely, although not altogether, due to the combined or alternate and always associable play of the nervous mechanism which we have examined. Such nervous action even under abnormal circumstances may be rhythmically or arrhythmically exerted.



Reduplication of the second sound of the heart may at present be excluded from discussion, as it may be wholly due to hydraulic variation in the pulmonary artery and aorta. Triplication, however, otherwise termed *bruit de galop*, cantering rhythm and reduplication of the first sound of the

[8] Haliburton, op. cit., p. 670.

Digitized by Google

heart, while it is capable of being influenced by gravitational conditions and modified by posture, is essentially a retarded systole, or in some cases a systole followed by a very small supplementary systole which for definiteness may be termed a "hypo-hemisystole" or something less than a hemisystole. Like variation induced in the pulse-wave by respiration, the neutral factor is necessary to its production, as we may convince ourselves comparatively satisfactorily by a study of the more pronounced condition to which it is related—namely, quadruplication, or one of the forms of rhythmically dropped beat. (Fig. 3.) Reduplication of the first sound

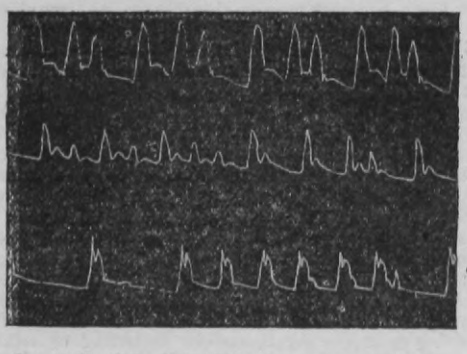


FIG. 3.

a, Occasional quadruplication. *b*, Regular quadruplication. *c*, Triplication with anacrotism.

has been variously accounted for. Dr. Sibson[9] considered it to be due to asynchronous action of the two ventricles, and Sir William Broadbent has recently expressed the same opinion.[10] Physiologists, however, such as François Franck, dispute the possibility of dissociated ventricular action, and clinical examination and sphygmography appear to me to support the physiologists. Two ventricular systoles would of course mean two diastoles and reduplication of the first sound on Sibson's hypothesis should usually be associated with a reduplication of the second sound which it is not. But were the double systole situated in the left ventricle it would not necessarily imply a reduplication of the second sound. Now, sphygmography shows that cases of quadruple pulsation consist of a long systole followed by a short diastole and this by a short systole followed by a long diastole. (Fig. 3 *b*.) Systole, in other words, is followed by hemidiastole, this by hemisystole and this finally by a long diastolic pause. The tracings I throw on the screen will emphasise these points. It has been observed that digitalis induces this rhythm in some cases and this fact, it

FIG. 4.

a, Quintuplication. *b*, Irregular hyposystole. *c*, Occasional acyclia.

appears to me, supports a neural view of its causation. When the beat is triple and the first sound reduplicated these events are crowded up, the first short diastole is omitted and the triple rhythm with anacrotism results. (Fig. 3 *c*.) Instead of the bigeminal pulse of quadruplication, a trigeminal pulse may be present which consists of three systoles and two diastoles. It is a quintuplication. (Fig. 4 *a*.) In all these varieties the ventricles act together, not apart, and the regulating factor in the rhythm is, I believe, neural. The cardiac cycle may, we know, be altogether or almost suppressed, and this acyclia it may fairly be argued is a variety of inhibition and probably not only neural but more precisely pneumogastric in origin and due to local cardiac or distant reflex stimuli. (Fig. 4 *c*.)

Some of the varieties of abnormal cardiac rhythm mentioned may be of long duration, but they are essentially an adaptation of the organ to certain circumstances with a view to carrying on the circulation, and while they may at times be significant of cardiac failure they are not necessarily so and cannot therefore be regarded as pathological. It is not so in some cases of persistent *bradycardia* and *tachycardia*. In the former, as we know, the heart's action is abnormally retarded, the neural cause of such retardation being, it would appear, either *in* the heart or *outside* the heart. Dehio[11] showed that extra-cardial bradycardia could be accelerated by the administration of atropin and that what he terms cardial bradycardia could not be so affected. It is the latter kind which constitutes the graver danger to life. (Fig. 4.) The precise neural mechanism of the condition can only be surmised not having yet been demonstrated. Retardation should normally provoke acceleration, and as it does not do so it would appear in the absence of myocardial degeneration or some general depressant such as a poison, whether auto- or hetero-genetic, that the seat of the disorder is in the spinal visceral innervation of the heart, an examination of which will probably ultimately reward the labour of someone. The transient bradycardia which follows fevers such as pneumonia may be attributable to exhaustion of the spinal visceral nerves, and Goldscheider and Flatau[12] have recently shown that high temperature has a very distinct effect upon the appearance of central nerve cells. We know, however, as little

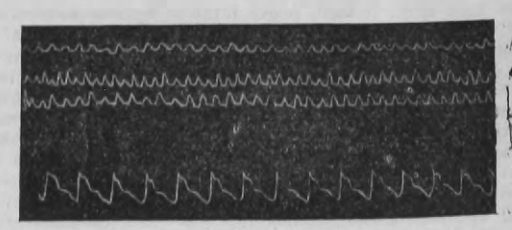

FIG. 5.

a, Persistent cardial bradycardia. *b*, Bradycardia with quadruplication.

positively about the essential neural causes of bradycardia at present as we do of those of persistent *tachycardia*. These very terms reveal our ignorance. There is some reason to believe, however, that persistent tachycardia like bradycardia may be of cardial and extra-cardial origin. My former colleague at the Great Northern Central Hospital, Mr. Spencer Watson, cured a case of persistent tachycardia by the removal of post-nasal growths. Martius also in his monograph has collected a number of cases in which a degree of persistent tachycardia was associated with disease of the pneumogastric nerve or nerves. I have already suggested that in some cases of cardiac dilatation associated with

FIG. 6.

a, Essential paroxysmal tachycardia. *b*, Sphygmogram from the same case showing the sudden restitution of normal pulsation.

persistent tachycardia a neural stimulation of the rich nerve-supply of the heart may be active in producing the condition and it is a common experience that the removal of dilatation also reduces the heart-rate to more leisurely and regular

Digitized by Google

action. In essential or paroxysmal tachycardia, however, we have an interesting nervous condition, at present unexplained but usually associated with cardiac dilatation, in which the delirious heart appears to escape from all nerve control, inhibitory and accelerant, depressant and augmentative, and to revel for a time in the fœtal tic-tac of emancipated visceral rhythmicality. (Fig. 6.[13]) This form of run-away heart is usually pulled up sharp by what appears to be an augmented inhibitory action of the vagus which asserts its authority with surprising abruptness. The sphygmograms I show illustrate these phenomena. This sudden restitution to normal visceral motion is not unknown in other organs. The defective biliary secretion of non-catarrhal inhibited hepatic motion may be rapidly followed by normal secretion. The oliguria of an actively podagral state may as quickly be succeeded by copious urination just as the mental irritability of suppressed gout may suddenly lessen when the disorder finds localisation in a joint. That these rapid changes may be due to neural conditions there is good reason to believe. It is related of vom Stein, the patriotic and able opponent of the First Napoleon, that when he was dismissed by the King of Prussia at the dictation of the ill-mannered Corsican he developed a bad attack of gout which resisted all treatment, balneological and other, until Queen Louisa, overruling the complaisance of her not too heroic consort, procured vom Stein's recall to office. The gout disappeared forthwith and the metabolic and excretory cripple of yesterday, restored to mental and bodily vigour, successfully organised the overthrow of the insolent invader of his country.

Just as visceral disorder may be the stimulus underlying somatic sensory phenomena, so also somatic motor phenomena may be due to visceral disorder. Irritative, septic, and stagnant conditions in the gastro-intestinal canal may apparently be the efficient cause of clonic and tonic disturbances of the somatic muscular system. In the case of the myoclonus multiplex which affects some neurotic and neurasthenic dyspeptics it is probable that these painless spasms are due to some general irritant in the blood, frequently aggravated by a certain amount of tabagism. But the question of reflex of unabsorptive and toxic origin in wide-spread tetany is more difficult to decide. The bilateral tetany of the infant, for example, with carpo-pedal contracture so frequently observed at our children's hospitals, and usually in association with gastro-intestinal irritation of a pronounced type or with the recent history of such, might very plausibly be argued to be a reflex due to bilateral stimulation of the bilateral innervation of such a single tube as the alimentary canal. This view is moreover still more plausible in those cases in which the higher centres are quite unaffected and the patient grins complacently at his carpo-pedal condition. It is, however, possible that there are toxic agents which in certain quantities act like strychnine chiefly upon the spinal cord and the alcoholic extract obtained from the gastric juice by Bouveret and Devic[14] seems to have been capable of producing tetanic convulsions on intravenous injection. The motor disturbances, moreover, need not be limited to the lower segment of the nervous system but may, according to the authors quoted, become generalised and even attended by epileptoid phenomena and unconsciousness. Under these circumstances, however plausible at first sight a reflex explanation of tetany may appear, it is probable that the toxic view now more generally entertained is the correct one. In minor degrees of the affection it is just possible that reflex action may also play a part. In any case the intimate connexion between the visceral disorder and the neuro-muscular phenomena in question is indubitable. Whether some cases of somatic contracture of a so-called "hysterical" nature are of visceral origin cannot be stated positively, notwithstanding the large *rôle* previously assigned to the sexual system in these disorders. Renal calculus may, however, provoke a lateral contraction of the trunk on the affected side[15] which must be regarded as a true reflex and I have observed the same condition in a neurotic patient the subject of consolidation of the base of the left lung due to aortic valvular disease. The length of time for which "hysterical" contracture may persist removes auto-intoxicant influences from the purview of causes, and the final discovery in some cases of central sclerotic changes indicates the possibility either of original disease there, or of so-called functional changes becoming organic lesions, whether the original stimulus were splanchnic or not. The somatic hysterical contractures bear a very strong resemblance to an interesting group of cases which Mr. Clinton Dent brought before the Medical Society of London in 1897[16] in which a spastic condition of portions of the alimentary canal may simulate tumour, cause severe pain on the principles laid down in a previous lecture, and even justify the operation of laparotomy from the urgency of discomfort. This intestinal neurosis or contracture appears like its somatic equivalent to be in the first instance reflex rather than due to a more general poisoning of the centres.

In bringing to a close this course of lectures, of the many defects in which no one can be more conscious than I am, I have again to express my thanks to the Fellows of the College for the indulgent courtesy which induced them to appoint me to the office and to pray that the leniency which they have already shown may suggest excuses for the inadequate manner in which I have executed my task. I am aware that I have touched but the fringe of a great subject of entrancing interest and supreme moment, the better knowledge of which is calculated to have an important influence upon much that is of interest to us as men and as physicians. If, however, in their opinion I have added anything in the course of these lectures to such knowledge—if, buried in the worthless quartz of much nebulous hypothesis, they should deem it possible to detect some grains of golden truth—I shall feel happy in believing that my labour has not been altogether in vain and that I have shown myself sensible of the honour which they have conferred upon me in appointing me to the lectureship.

The Harveian Lectures

ON

DISEASE, ITS TREATMENT AND THE PROFESSION OF MEDICINE IN 1899.

Delivered before the Harveian Society of London on Dec. 1st, 8th, and 15th, 1898,

BY WILLIAM EWART, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL AND JOINT LECTURER ON MEDICINE TO THE MEDICAL SCHOOL; SENIOR PHYSICIAN TO THE BELGRAVE HOSPITAL FOR CHILDREN.

LECTURE III.[1]

Delivered on Dec. 15th.

EDUCATION AND MEDICAL PRACTICE: THEIR PRESSURES AND THEIR PROSPECTS.

GENTLEMEN,—Our attention is claimed to-day by the medical profession, its labours, its difficulties, its prospects, and its rewards; but the future of medical education and some questions of practice bearing upon our status will be dealt with more prominently.

THE PROFESSION AND ITS MEMBERS.

It has been said with truth that we are all debtors to our profession. We are associated with its great achievements and taught to appreciate them, and we are conscious also of an honourable participation in all its good works. Lastly, unlike what obtains elsewhere, a livelihood is fairly assured to all. There are, however, material concerns which through pressure of daily avocations are often imperfectly safeguarded or, may be, treated as secondary. Yet for the majority there was a practical purpose in the selection of their career. A few inherit medical traditions and grow up in a medical atmosphere; for them medicine may be a "calling"; for the remainder it is an "opening"; and once they have engaged upon their lifelong labour the material aspect of things cannot be ignored. How closely this object is connected with our professional position will be made clear as we proceed.

[16] Transactions of the Medical Society of London, vol. xx., p. 257.

[1] Lectures I. and II. were published in THE LANCET of Dec. 17th and 24th, 1898, respectively.

OUR PRESSURES AND OUR REFORMS.

Witnessing disappointments and failures in every walk of life it would ill become us to complain of personal hardships or of those purely professional difficulties to which I shall allude. They may be regarded as transitory. The profession is undergoing "a cure of discomfort by counter irritation" which is but a stage in the return to a healthy state. Our pressures are of two kinds: (1) those exerted from outside by the public, by the State, or by the conditions or fashions of our time; and (2) those from within, our internal reforms, always well meant though liable to defects and to the need for readjustments. The lateral pressures have been sufficiently dealt with. Our worst pressure, however, has been from below and it is to this that we shall presently revert. From above our limitations arise from too much or too little legislation; and of late instances have not been wanting in which the unreasoning opposition of the uneducated vote and that from noisy or hysterical sections have been brought to bear against our action with the sanction of the law. Thus some of our professional events have been retrograde, with great detriment to public advantage, to national credit, and to personal safety. I need not dwell upon recent achievements such as the ticket-of-leave given to small-pox and syphilis and the setting back of the clock of experimental science. These evils were avoidable. Fortunately they may yet be remedied except for the loss of irrevocable time. Compared with the dealings of those well-ruled nations whose progress is not allowed to swerve from common sense and who follow a straight road to any social object we are in this country, thanks to these manœuvres, left hopelessly behind, electing to follow when we might lead. These risks and delays are the sport which delights a free people and which by way of compensation may perhaps keep us active and in fighting condition.

The lateral pressure will probably be relieved for the growing generation. The world is expanding at a rate for which there is no parallel in history. Looking back four hundred years, the discovery of America occasioned great developments and the treasures torn from the harmless natives went to feed the growing trade of the world. But the conquerors alone reaped the benefit and civilising operations were slow to compensate the vanquished for the barbarous inflictions of conquest. The exploration itself was not rapid and occupied many years. In our times an entire continent has not only been explored within a few years but is being wired and railed and the machinery of civilisation called into existence simultaneously at many centres. For this growing world medical aid will be requisite. China also may offer a large field where the English physician may come into fashion. The colonies, especially those where gold is the attraction, are only beginning their period of expansion. But we must realise that Canada, Australia, and New Zealand are no longer dependent upon home supply. They are now medically self-supporting; the pupils of their universities come home for the study of special subjects and to watch our clinical practice, but they are already fully qualified and their numbers are sufficient for the local needs.

Our internal reforms.—Other reforms are of our own making and the chief of these bear upon medical education and examinations and the rules which govern our mutual relations and our relations with the public and the State. Well considered and measured to suit the times, they may not be permanently adapted to meet all future needs; but they cannot be again modified until after a period of friction which makes us long for the next change and yet dread the unknown complications which it may cover.

PROFESSIONAL ALTRUISM AND SELF-SACRIFICE.

To practise medicine is to learn that our lives belong to others rather than to ourselves. There is an increasing altruism in the lives of most men, but a great deal of this is unconscious and passive, and the mass of mankind are unaware that they are wearing themselves out for the sake of others. Our altruism is both conscious and intended; it is an active altruism, which contrasts with the ways of diplomacy and of commerce. It is indeed a unique sight, that of a whole profession working strenuously for the sake of its fellow creatures at the systematic destruction of its own means of support. Is any disease voluntarily allowed to survive in the individual or the community, any contagion given free scope, any sanitary defect uncorrected, any oppressive or deleterious conditions of labour allowed to proceed unchecked? It is left for others outside the profession to marshal every resource of ignorance and prejudice for the purpose of keeping alive fatal diseases. To them the medical profession might have been thankful, but in our medical press we find only indignation at the resulting waste of life, of health, and of happiness.

The same unreckoning policy has led us to instruct our patients in practical matters of health. Institutions for teaching the principles of hygiene and elementary treatment and first-aid societies have been founded all over the country, every opportunity being utilised to spread among the public ample knowledge of the arcana of medicine, and with the same view medical writers are now lending their pen to the press.

The lateral pressure in our ranks.—But there are limits beyond which generosity itself ceases to be wise. The quality of work deteriorates when instead of strengthening it wears the labourer, and to avoid this is of importance, not alone to the profession. While the earnings of other workers have been rising with the general increase in our national prosperity the reverse has happened with us.

Events have brought about difficulties for which none can be held responsible. All sections of the profession have felt them, each section imagining itself to be the only one to suffer. To put the matter briefly, there may not be too many medical men, but whilst there might be work for all this is neither evenly apportioned nor remunerated. Of the two chief contributory factors the overcrowding of the profession is to my thinking the least. In proportion to the population our numbers are not so overflowing as in some other countries nor are they much greater than at earlier periods. But the opportunities for practice have been restricted by science and by charity. And it is now manifest that by seeking some relief from these difficulties in the provident system individual members have helped to restrict the supply of employment for the profession.

THE PROVIDENT SYSTEM AND ITS PROBLEMS.

In its ideal form this system seeks to secure the greatest good to the greatest number, benefiting alike the deserving poor and the profession. It seems to have been an early social development in China, dating beyond the commencement of historical times. In this country it is largely a growth of the second half of the century. Its principle is the insurance of the healthy against the expenses of future illness. That principle has been accepted by the profession as belonging to our scheme of usefulness and as tending to professional advantage if only it were fairly worked. The progressive development of the system and the increasing growth and prosperity of the provident societies is a spontaneous testimony to the worth of the medical advantage secured, but for the profession there has been more promise than realisation.

Our services are for many a necessity and it is right that they should be within the reach of those for whom they are intended. The poorer patients have five courses open to them: (1) some of them are sufficiently near the margin of pauperism to enable them to obtain Poor-law relief; (2) many apply to the chemist for advice and medicine, and this largely keeps up the practice of counter prescribing; (3) others are anxious for treatment by hospital physicians and surgeons and endeavour to obtain it at the hospital for which they have a predilection though this may not be the nearest one to their own home; (4) a large number enrol themselves in the lists of the provident dispensaries and of the clubs; and lastly (5) others prefer to get their advice independently and at the time when they think they need it. If the medical man's charges should be prohibitive he would drive this humble practice into the other channels which have been indicated. In order to meet the necessities of the case there must be for his advice a sliding scale within the reach of the humblest means. This unavoidable smallness of remuneration is a reason for his preferring a system where it is to a certain extent disguised. On our side it is a wise provision that the healthy, whilst able to do so, should contribute to the support of the profession whose services they will require when stricken with disease. Payment from the healthy instead of from the sick is, indeed, a principal admirably adapted to meet the crisis. This alone would prove an attraction; but there is a further inducement in the advantage of actual work. Unfortunately the slender compensation has been only partially reaped by the profession. Benevolent in its intent, coöperation has opened the door to

Digitized by Google

novel dangers and abuses of which the practitioner is ultimately the victim.

The risk to independence and remuneration.—Our prestige is endangered by any hard-and-fast compact which places a definite value upon services. The contract is then apt to be regarded as a commercial transaction in which both sides are supposed to obtain an equivalent. The sentimental reservation may be kept in mind by one of the contracting parties. It is but too likely to be lost sight of by the other and from a strictly legal standpoint it may not then appear that the payment is not a full compensation but an honorarium only. The medical man's position is no longer that of unrestricted freedom and his place not easy, as at the best the bargain is a hard one. If the scale of remuneration should be unfairly low the growth and prosperity of the societies would entail a proportionate extension of the attendant injury. And when the hardship of inadequate payment has once been submitted to there is a danger that the curtailment may be made yet more severe. This downward progress as well as the low level now reached are the serious aspects of a system which we may look to the coming century to ameliorate.

The provident associations.—The beneficent institutions known as dispensaries seek to be self-supporting, but a charitable interest is taken in their management by members of a richer class, and this is a saving clause, for much depends upon the spirit of those who administer as well as of those who receive the relief. The collateral advantages which are often opened up by those who serve a well-conducted dispensary render it a matter for regret that it has not been found practicable to extend them to all the local practitioners or at least to as many as may wish to participate. The remuneration itself is small, but it is fairly divided according to the work done. The difference between these institutions and the *friendly societies* is fundamental; in the latter the softening element of charity is less prominent and that of sentiment in not included. In early days the medical man's willingness to help them may have been considered a favour. This is now changed and they have not always refrained from turning his difficulties to account. Other associations built purely upon the principle of commercial insurance, although businesslike in some directions, are free from any scruples connected with medical etiquette and in other directions there is even less regard than in the friendly societies for the individual interests and for the professional dignity of the medical officer.

The prevalent abuses.—The defects which have arisen are clearly unintentional and the outcome of ordinary economical principles, the societies seeking their corporate interest and securing it, whilst the practitioners have too often unwarily sacrificed their advantage. They include: (1) the obviously inadequate remuneration for excessive work and responsibility and the partial payment which is sometimes made when it should be made in full; and (2) the unjust appropriation of advantages intended for the poor by those able to pay. Were the charitable ministrations bestowed only on the deserving poor their cost would be a lighter burden. But it is well known that owing to imperfect checks and to the failure to realise the fault of which they are guilty many thoughtless individuals receive relief who are really able to pay a fair honorarium for private attendance, and this is contrary to the intentions of those who manage these institutions. A friend from the provinces reports to me an instance in point: "A farmer in quite a large way was in a club. After being ill for a year he desired to employ a private medical man, to whom he then paid 3*s.* 6*d.* or 4*s.* a visit. Thinking he would like still further advice he paid five guineas as a consultation fee with the greatest readiness. The medical officer must have travelled several miles of bad road to see this man, the only payment being less than cab hire." The same friend also writes: "Years ago most clubs' contributions were at the rate of 5*s.* per annum per member and that when wages were much lower than now and when membership was confined to the genuine working man. The working man earns more and pays less." ..... "Many clubs unfortunately have lowered the subscriptions to 3*s.* 6*d.* per annum." This abuse is not sufficiently guarded against in the organisation of the clubs. Some men of substance are admitted as members or retain a membership assumed in less prosperous days and do not refrain from getting their medical advice at an almost gratuitous rate. The practice of others is thus made to suffer besides that of the medical officer, for should he fail to meet cheerfully the behests of his employers, or refuse to submit to a reduction, the club may find a stranger to fill his place, and this will mean for his *confrères* additional competition in an already restricted field of practice.

The worst troubles arise in connexion with the medical aid societies. They actively canvass the public. Their medical man is advertised, not always fairly, it is said; but he may have to suffer for the advertisement. And the climax is reached when he is victimised not only by the societies but by intermediate agents. Instances have often occurred when agents have induced people to insure and to transfer themselves from the private list to the club list of the same medical man. It can hardly be doubted that funds have gradually accumulated out of the profit on the medical officers' work. In the case referred to by the same informant they did not get more than two-thirds of the payments made to the medical aid societies, whilst the least that should have been done was an equal division of the surplus after payment of working expenses. Illustrations such as these will suffice to show the mode of injury suffered by the profession.

The detriment to the profession.—Diminution in practice goes hand in hand with a lessened value set upon professional services. But the worst aspect of the whole position is the further decline in dignity and emolument due to the fact that, small as may be the pittance, it has its market and that any competition can only lower its figures. The low value which is thus forced by contract reacts upon the remuneration of others who but for this would have been in a position to resist the unmerited depreciation of their services. This means, moreover, a progressive reduction in the opportunities for private attendance upon paying patients of the humbler class, and this reduction tells even more upon practitioners who are not connected with the clubs than upon those belonging to them. Thus special correctives are needed against the evils known as the tyranny of the clubs, the lowering of the fees by competition, the exploitation by medical aid societies, the underselling of medical work, the insufficient wage limit, and also the admission of women and children at a lower subscription than men though they need more attention and previously contributed to private practice.

The remedy.—The continued expansion of the insurance system renders imperative some early provision for that minimum scale of honorarium which shall safeguard the public and the profession and for the adoption of an efficient wage limit. Where is the remedy to come from? Its possible sources are State interference, corporate action, independent combination within the profession, which might be purely local or more general, and education. Some action has already been taken, especially in the direction of local combination; and much credit is due to various local groups for their energy in resisting the pressure of powerful bodies. Though the action has been a purely local one the example may tell at a distance. Indeed, it has suggested the idea of an extended combination which might include representatives of all local associations and through them of all practitioners interested in the provident system. A totally distinct action has also been proposed—that of State aid in this difficult matter. This is a remedy not without a danger, for if the State is to come to our assistance in the details which we ought to arrange for ourselves it is possible that its inelastic control might fall heavily upon us and trammel us when it would be much to our advantage to be free. But leaving State control aside there remains the official action of the professional governing bodies who alone can speak for the entire profession. If I mistake not there is a strong feeling abroad that these difficulties should be noticed officially, but others are inclined to think that the profession ought not to be committed and that independent combination should be able to provide a remedy. Between courses so different it is difficult to choose. One of them pledges the profession, the other allows free scope to self-government without the assumption of too onerous a responsibility.

Among various suggestions in connexion with combination one worthy of notice is made by the Special Commissioner of THE LANCET:[2] "The best method for abolishing medical aid associations, clubs, &c., is for the profession to establish a model institution of its own open to all local practitioners and managed exclusively by the medical men themselves. Then no practitioner would have any excuse for selling his services to a speculating commercial concern; if he wanted

[2] THE LANCET, Oct. 29th, 1898.

Digitized by Google

club patients he could join the public medical service. All patients who could not pay the usual fees would have the option either of joining this institution as subscribers or of claiming relief under the Poor-law. The battle of the clubs would be terminated, for the medical clubs would cease to exist." This proposal suggests a new field for professional activity. In itself the idea sounds practicable so long as care is taken that we are not involved in any undertakings outside the scope of the profession. Self-help is sound policy, but in this matter it is regarded with good reason as unequal to the task. There is a difficulty in repudiating arrangements firmly rooted in localities and any efforts in that direction are but too likely to be defeated by the action of members of the profession who are outside these local combinations. To meet this difficulty it is not to be wondered at that the General Medical Council should be appealed to for an exercise of their power to register and approve those arrangements which have been found by experience to be most suitable to the various districts and to restrain registered practitioners from an unprofessional intrusion which tends to render joint efforts nugatory. This would doubtless afford the easiest way out of the present complication provided it could safely be resorted to without prejudice to our future. It must not be forgotten that a march has been stolen upon the profession owing to individual members having entered into treaty with organised societies. It is to be feared that the local combinations must remain hampered by the influence of these unfortunate beginnings and that their proposals might not come up to the level which the profession may have in prospect when the time comes for corporate and entirely representative action. In view of that object it might be undesirable that the profession should stand committed to any adjustment arrived at locally or even by a combination of many local groups. Indeed, there might be a danger lest any larger combination might wear in the eyes of the public an importance other than that which it claimed for itself and be thought to carry a mandate from the profession. In this respect there is perhaps an advantage in combination preserving for the present its purely local character.

The reasons for delay.—In favour of a policy of waiting the fact should be remembered that we are still within the period of transition and that we cannot yet foretell the proportions which the coöperative movement may ultimately attain. How best to deal with the great question is another uncertainty. Should it be by means of unofficial combination within the profession or by the action of our representative authority, the General Medical Council? If by the former method practical conclusions may be obtained at an earlier date, but they may be found to have fallen short of the requirements which the future may disclose. If by the latter considerable delay can hardly be avoided but the value of the result would be the greater in proportion to the time involved in its elaboration. One point appears to be clear. Any final settlement should be made on an independent basis. A privilege usurped, however unintentional the usurpation, is not from the standpoint of the injured party a fair basis for negotiation. All local attempts at readjustment must suffer from this disadvantage. It must be made evident that the profession repudiates the estimate which has unfortunately been placed upon the value of the services of its members through the accident of circumstances even more than owing to unguarded action on the part of a few. Though I may not have much support in leaning towards cautious delay in any comprehensive handling of the difficulty I feel sure that I am with all of you in thinking that its study cannot be safely postponed and that it should engage the earnest and early attention of our authorities.

The remedy from education of the public and the profession.—There is a different remedy, most effectual, but slow—the teaching and the appreciation of that which we owe to ourselves and which is due to us by the public. On our side the great body of the profession are guided by those high principles which are being universally taught. The dangerous few must be either educated up to its level or kept out. It is difficult to overrate the influence which can be exercised on the minds and dispositions of our pupils whilst they are passing through the medical schools. More may be done perhaps to raise in their youthful mind a superior ideal of the dignity and of the unity of the profession. Men cast in this mould might be allowed to shape the higher interests of the profession wherever they go. Much more general is the lack of due appreciation on the part of the public, especially among the lower classes who are not unlikely at times to misinterpret the most charitable intentions. Literature might do much to enlighten them as to our position; and in the recent lofty achievements of the profession there is a theme which, if properly handled, might work in the direction which is wanted. The remedy would thus consist first and foremost in the cultivation of a high ideal in the study of medicine, and in the second place of the authoritative influence which combined action might exercise upon the press.

MEDICAL EDUCATION.

The aspects of this subject which you are invited to consider are the professional examinations and their standard, the general scheme of studies or curriculum, and—not least important—the preliminary examination.

Examinations are a necessary evil. The public must be protected and a mass of important facts must be grasped by the student. But under this load the freedom both of study and of teaching suffers and imagination and original thought are less developed than memory. I would be the last to criticise adversely the present system. It is regarded by those able to judge as the best that could have been framed and as a vast improvement upon all previous attempts. It must command admiration in respect of the completeness of the teaching and of the amount of the knowledge required. But we have recently heard it from great authorities that the burden of scientific facts is becoming intolerable for the student of medicine and that some part of the burden must be removed; and in anticipation of a yet distant revision it may be permitted me to bring forward impressions gathered from some observation of the student and of his work, especially in their clinical aspects. A few advances in that direction would bring us almost within reach of a very perfect system. Clinical work is for us all the essential and the almost entire professional function; and the difficulty is how to give it a share not altogether disproportionate to its importance, since, without exaggeration, it might claim attention during the entire period of medical education, whilst in that time a vast number of important subjects have to be dealt with.

The preliminary examination and the recruiting of the profession.—The entrance examination is our Rubicon—not to be crossed without influencing the fate of individuals and of the profession. Parents, and particularly those who belong to the profession, are anxious to start their son without delay on his long journey through the curriculum. But in his interest quite as much as in that of the public and of the profession our gates should not be thrown open too widely lest he should be caught in a groove in which, as time wears on, he may find neither success nor escape. Physical strength and staying power are needed, not only for medical study, but yet more for practice, to meet the fatigue of country work or the constant worry in town. Unusual gifts of the mind never were essential, but weak or imperfectly trained faculties should exclude. Now more than ever endless painstaking and endurance are the chief requisites. Medical students need not be picked men, but tried men they should be; and to ensure this is the chief office of the entrance examination which at the same time might be a means of checking an excessive supply. To those familiar with its difficulties the study of medicine seems to be too lightly undertaken and with insufficient preparation. In the navy professional life begins quite early and the studies are thenceforth directed towards the profession.

A similar early direction of the studies of the future pupil would relieve some of our troubles. Far from there being any idea of cramping his preliminary education there are practical and useful subjects, such as chemistry, botany, zoology, and geology, which would expand it. Our opportunity is to frame an entrance examination which should test the men as to their fitness for their future labours but should not demand of them anything wasteful from the point of view of their life's work. On the contrary, this examination might be rendered practically useful in relieving as much as possible the overloaded curriculum. An utilitarian position has been openly taken up in connexion with the preliminary examination and it was thought useful to sacrifice the ornament of a classical education as a necessary accomplishment. It remains doubtful whether the promise which had been held out as a compensation has been fulfilled. Though the study of Greek is discredited the ability to trace in a Greek dictionary the meaning of

Digitized by Google

professional terms must appeal to reason as a requirement so long as our medical nomenclature is chiefly Greek. Since Greek is not an absolutely dead language it might perhaps be taught in the elementary proportion needed on a modern basis and without much loss of time. The utilitarian reform seems to have stopped short at this sacrifice of the classics. Yet there are studies now neglected in the curriculum the rudiments of which should not be entirely unknown to members of a learned profession—I refer to the elements of botany, of zoology, and of geology which are most desirable. If made compulsory together with chemistry and physics in the schedule of the preliminary examination these subjects would be useful to the student and educationally they would be some compensation for the loss of a classical training.

The curriculum.—How different medical education in the days when the curriculum was of two years and examinations were such as to suit that training! The curriculum was extended to three years and for a long time it was nominally four years, but in reality much longer for most students. The greatest improvement in medical education is the recently introduced five years' curriculum. This extension has already produced the best results, yet so much pressure remains that some change may become necessary early in the next century. The subjects are so numerous that they hardly fit within the period and from examination to examination the candidate has to slave to the end of his time. The question arises whether the best use is made of the additional year and whether a special claim upon it could not have been established in favour of our professional training so long and increasingly sacrificed to the preliminary subjects.

The old-fashioned apprenticeship was given up long ago without any equivalent as a substitute. It is impossible that we should ever return to it. Yet it was a thoroughly practical though primitive method of learning as much of the profession as the local opportunities allowed. When the apprentice came to town he was for his years a man of practical experience and in looking back upon his early difficulties and doubts he could appreciate the value of the theoretical knowledge to be gained in the dissecting room and in the wards. In that arrangement the supply of scientific knowledge was scanty but there was little waste from the point of view of utility. This distribution of the student's work has been completely reversed, but the partial sacrifice of the practical professional studies was the unintended result due to the desire to cultivate a higher science in the service of medicine. Unfortunately, for a long period the teaching of the sciences had to be theoretical and by lectures without any practical participation on the part of the learner. Thus the student, deprived of his apprenticeship, spent his early years in studying practical science in an unpractical way. When he joined the country practice as a qualified man it was the old apprenticeship over again—most things practical yet to be learnt—only the apprenticeship was at the wrong end of his time.

The academical and the utilitarian idea.—The present system might be regarded as "academical" to a fault. The subjects are dealt with as it were in compartments. The pupil is taken through each of them from its beginning to its end. This development was greatly stimulated from our seats of learning and in part reflected from universities abroad. Science was to be taught along systematic lines rather than towards any lateral goal of temporary or limited usefulness. The old universities have now given a practical turn to the academical idea and the medical schools throughout the country have laudably followed this intention, but not always with the necessary facilities, and in spite of a dearth of that first of all requisites, time, on the part of the student. Thus he has often had a complete course, but, as in those hasty visits to the wonders of the world, little of the inside of things may have been seen by him; he might perhaps have done more for himself had he attempted less. Too often also the teaching of valuable elementary subjects is practically divorced from their uses; and when the time comes when the chemical, the physiological, and the biological learning and methods might have been of practical value they have been forgotten. Often the ordinary student does not seem to connect the idea of the methods which he has applied in the physiological laboratory with the self-same methods as used in the wards. This would seem to suggest the desirability of associating, though not at too early a date, a medical purpose with the teaching of anatomy, physiology, biology, and chemistry, and to render their applications more clinical.

Method, which represents the academical idea, is essential; but it matters comparatively little in which field the mental powers are drilled. Any of the sciences well learnt, but particularly anatomy and physiology, would serve this educational need. But the utilitarian or professional idea looks to those few great principles and facts without which no physician or surgeon ought to trust himself to work as those upon which the main stress ought to be thrown in the teaching of the sciences. With these at his command the pupil might progress by imperceptible degrees to a higher level of scientific and clinical efficiency, and the acme of his scientific training would be the study of practical pharmacology which combines all the sciences bearing upon medicine. Here the better men would find their opportunity for individual research and intelligent clinical work would be stimulated.

We do not notice any progression of this sort in our present system. Whilst elementary physiological matters are imperfectly grasped some of the most difficult problems, those which tax the expert, are made the study of the beginner. For their due appreciation his highest level of scientific training and experience, his later periods of study, are best adapted. There is much to be said in favour of reserving these higher scientific developments as a reward for the veteran student. The younger student's practical work in laboratories might with advantage be concentrated upon those methods which are of practical use, further knowledge being added upon a firm foundation of facts previously known. Thus, whilst avoiding the risk of a premature entry into the wards it might be useful to shift a great deal of the practical physiological work from the physiological to the clinical laboratory. Work performed there in connexion with the examination of the urine, of the blood, of the physical conditions of the normal organs—a subject hitherto neglected—the study of the heart sounds independently of murmurs, of the respiratory sounds when uncomplicated by disease, of the position of viscera as recognised by palpation and auscultation would never be regarded as wasted either by the student or later by the practitioner and would be useful additions to the practical work of physiology. The full practical apprenticeship of the young clinical student would comprise a period of work in the physiological, in the chemical, and in the pharmaceutical laboratory. But for the greater number the chief apprenticeship would be that in the clinical laboratory, where he would acquire at an early date familiarity with those methods and apparatus which belong to his own future work.

Clinical laboratories in connexion with teaching hospitals are a great need for students and for research. Whilst in this country most philanthropists have made it their ideal to supply a sufficient number of beds and have overlooked the real pauper in the hospital, science, and the real need, that of the knowledge for curing the diseases which are put into these beds, a much clearer view of things has long prevailed on the other side of the ocean. Practical sense has made it obvious that the object of hospital treatment is not euthanasia but recovery, the secret of which cannot be learnt without the means of study. The time cannot be long delayed when the necessity for a clinical laboratory for all hospitals, however small, will be recognised in this country. And when this need is more widely understood among us generosity will soon flow in this neglected channel. In medical schools clinical laboratories should be of adequate size and completeness, but special research must continue to be conducted in laboratories or institutes of a more elaborate order. Of these we already possess a few at our universities in London and now at Liverpool. But many more are needed and there is ample scope for private munificence.

Clinical medicine.—The cry from the obstetric side is, "Give us more time to train the clinical pupil in the most responsible and important part of his future practice." A justifiable demand; but how can it be granted when clinical medicine itself is starved? Nominally three years are provided for clinical training, but too often after upwards of two years absorbed in the preliminary studies these subjects are forgotten and may have to be learned again at the expense of time properly belonging to clinical work. If the subjects are thus to overlap and to be blended after all would it not be economy to begin the clinical training earlier and to adopt the policy of a continuous and progressive study of anatomy and physiology, increasing stress being laid with

Digitized by Google

the progress of education on the higher aspects of both sciences as they bear upon clinical work?

The elementary clinical work seems to be too long delayed. After much time devoted to pure science and to examinations the pupil suddenly enters the wards unprepared. To him all clinical things are new. He is yet unfitted to utilise the advantages of a clinical clerkship which too often is conferred upon him at this stage. General elementary clinical practice is what he needs, not the exclusive association with two or three cases which he is unable to investigate for want of sufficient general experience of patients and of clinical methods. This he would quickly gain in the wards by contact with others of older standing whilst completing his knowledge previously acquired in the practical work of physiology and of chemistry. A few weeks spent in this way within sight and hearing of all that concerns disease and its investigation would enable him to take up with full profit the privileges of a clinical clerkship and to apply himself to the practical study of disease and of its treatment in association with the physician whose functions do not include the teaching of elementary methods. Inefficiency at the onset would be a less serious objection if the clinical clerk were prepared to retain his office until he had exhausted its opportunities, but he lacks time for this. Barely has he completed six months of this clinical work and he is taken away to other subjects without any chance of holding the valuable office again. In this way the most important part of a clerk's advantages are often lost to him and this accounts for the unfinished clinical condition in which so many have entered upon practice. The five years' curriculum might have mitigated this evil, and some men in their fifth year have sufficient wisdom to walk the hospitals when an opportunity arises, but the greater part of their time is claimed for other pursuits and no provision has been made in the schedule for the much-needed extension of the clinical training.

Medical education would gain much in being made more continuous by blending the clinical idea from a relatively early date with the scientific studies and by keeping up a progression in the higher studies of anatomy and physiology. The student would find interest and meaning in each laboratory method because shown to be connected with some clinical point and his clinical anatomy and clinical physiology would remain his valued and lasting possessions.

Clinical anatomy.—Anatomy, the "mathematics of medicine," will never cease to be indispensable and paramount among preliminary subjects, a fitting introduction to the most laborious profession. I do not know which is the greater wonder, the teaching of anatomy or the feat of learning it. Might not labour and time be economised? A thousand brains have been exercised as to how to render its study easier for the student on the old lines till we almost despair of ultimate success. Yet if it be true that elsewhere there are shorter methods we cannot afford to neglect any help.

Can "anatomy" be compressed or extended?—No part of anatomy is superfluous; but we cannot forget that for the sake of this completeness entire subjects are being thrown overboard. Some parts of anatomy are of supreme importance throughout professional life and the final examinations wisely require a knowledge both of surgical and of medical anatomy. But the average student has to learn these parts of the subject over again because meanwhile he has been allowed to forget them. The knowledge slowly and laboriously built up collapses like a house of cards as soon as the strain is over. If this is to be the result too much time would seem to have been claimed by anatomy at the beginning. The first year might suffice for undivided attention to the foundations of anatomy, whilst further instalments might be added by degrees and with a practical bearing. A study of the relations of parts might thus coincide with the teaching of operative surgery and medical anatomy with that of practical medicine and of clinical work. The term "clinical anatomy" includes both the surgical and the medical aspect. In both cases the long anatomical curriculum should lead as a net result to an accurate knowledge of those parts of the body with which we shall be professionally concerned. If the rest is to be finally forgotten might not its teaching be compressed? For the higher examinations a late application to anatomy has always been necessary and this shows that the suggestions thrown out are not absolutely unpractical.

Clinical physiology.—Similar considerations apply to physiology. In physiology we use too little our great opportunities of studying man. What would not Harvey have accomplished had he been armed with our present instruments and methods of investigation? Have we done full justice to his great example in cultivating physiological observations in the human subject? What should we think of a practical course on the circulation which did not include listening with the stethoscope to the heart sounds and learning accurately where they are to be listened for? Or shall we deal practically with splanchnology and not make ourselves familiar by palpation and by percussion with the position of the various organs? The ophthalmoscope reveals some of the processes of life without interference with their integrity and the laryngoscope equals the perfection of the ophthalmoscope as an instrument of demonstration. Practical physiology, taught as it is according to the happy tendency of the day by personal instrumental manipulation, would hardly be complete without a knowledge of these among all other physiological instruments. Their exclusion under any pretext would lay us open to the reproach of a deliberate neglect of those instrumental methods which are the only ones professionally useful to us. All this is the physiology which is essential—not abstruse or difficult or repellent—and these physiological observations, though so important and indispensable, are of a purely elementary nature. They might afford an easy rise to the higher, truly difficult physiological inquiries for which many a young student is at first totally unprepared and remains to the last unappreciative, whilst the living body appeals to every intelligent youth. These, therefore, are instrumental methods to which the student might be initiated early and a skill in which he might then have ample time to develop. Efficiency of this sort is child's play to the learning of musical instruments. It presents a little difficulty only for the less gifted minority and for them of all others it is important to provide a long apprenticeship. The advantages of such a system would be great and would tell at both ends. Early in his career the student would be awakened to a professional interest in studies which would henceforth assume for him in all their theoretical details a practical purpose. The gain at the other end would be incalculable. Instead of his helplessness in approaching the bedside the novelty of the situation and its strangeness would have long been removed. He would feel the confidence of an observer and might proceed to truly clinical studies of disease instead of wasting the clinical opportunity upon mere instrumental practice at the wrong time.

Centralisation and the one-portal system.—The continued agitation for reform has been a prominent feature of recent years. In this the profession has shown its earnestness in the cause of progress, in spite of the conservatism which renders it tenacious of its traditional independence, a conservatism bred of constant contact with nature and trained by the practice of self-government. Centralisation is the question of the day; it lies behind most of our present problems and in particular of those relating to university teaching, to the multiplicity of schools, to the variety of examining bodies, and to the relative value of the titles conferred by examination. The allurements of centralisation are great and great is the longing for it on the part of the categorical mind. But we may be well advised in not departing more than is unavoidable from the opposite system, perhaps less perfect in its form but more fertilising, a system to which we owe that which we are. Let us beware of sacrificing the vitality and spirit of our great professional bodies to the doubtful advantage of a monotonous uniformity. The one-portal system was some years ago even more urgently needed than it now is. Further improvement is necessary, but it is a question whether any radical change is indispensable. All that is practically wanted might be attained by all the corporations raising the standard of their examinations to a uniform level which would obviate any downward competition between them and at the same time would exclude from the profession, if possible at the entrance examination, those who are not thoroughly equal to its responsibilities, so that none but the fittest could get their names on to the Medical Register.

THE PLACE OF THE PROFESSION: ITS PROSPECTS AND ITS REWARDS.

The service to the individual and to the State.—I have dwelt upon the altruism of the profession in its constant war against disease. The character of the personal service rendered by its individual members is well known to us. It is often true, and not alone on the field of battle, that life itself

Digitized by Google

is offered in the hope of saving life. There is little wonder that our profession should supply a shorter average of life than any other. Alone, the medical man is never allowed to be ill and he is singular in continuing to work whilst ill. No other profession claims that its labour shall be carried on at night and on holidays and to this must be added the constant exposure to infection and to other risks. But it is not sufficiently realised that the work done by the profession in saving the life of individuals and in checking the spread of disease is a direct service and a direct gain to the State. Has its practical value been fully recognised? We enjoy, it is true, and are thankful for the favour and the protection of the State. But beyond charters and privileges such as are granted to great commercial associations working for their own profit and only indirectly for their fellow creatures and for the State little has been bestowed upon us. On the basis of this service we might as a profession be in a position to treat with the State. This was the custom with the ancient guilds. No such bargain has ever been submitted from our side. Men of medicine have parted with their "mystery" without even thinking of an equivalent which has not been proposed from the other side in the shape of any practical recognition. Whilst other professions act on the principle "Do ut des" the fruits of medical science which prosper our days of peace and ensure the success of our wars are a free gift to the State. And that profession which alone shares with the Church the direct care for the welfare of the community has little share in its honours.

The deserts of the profession.—Yet having regard to the value which the individual sets upon his own life, to the actual value which lives saved represent to the State and to the untold boon to humanity in the alleviation of suffering it is difficult to see what recognition could be adequate. In a younger world with such a record healers of the sick would have walked as gods among men. From the individual the medical attendant receives an honorarium only in acknowledgment of a debt which cannot be entirely paid. By the State this acknowledgment of debt is hardly made and the honorarium is scantily bestowed though statesmen admit that without a healthy population there can be no national greatness.

The place of medicine among professions. — Precedence between professions and their social status are regulated by custom and there is no desire among us to disturb these ancient traditions. It may be said of all professions that they have risen in dignity. In the case of medicine the rise in worth as estimated in vastly increased knowledge, in usefulness as judged from the amount of human life saved, and in influence as regards the practical reforms administered by the State under our guidance has been out of all proportion to any position which it has ever held. The end of the last century witnessed a revolution in France which brought to the front tumultuously the social layers by whom the chief work of the world had been carried on without recognition. Less turbulently but with unfaltering step medicine has been marching towards its proper place in the front rank of the professions. What is the medical profession in the State? Nothing. What should it be? The chief and most important influence. For it was truly said: "Sanitas sanitatum, omnia sanitas."

The reward: its deeds and its dignity.—The power silently wielded by our profession is ever increasing and must give it importance and ultimately a foremost position. For the present its reward lies in the consciousness of this fact, imperfectly realised by our fellow men; and also in its dignity, in its intellectual work, and in a knowledge that its ministrations are indispensable as well as beneficent. In this isolation and this consciousness of power there is a superiority. The profession if a self-made aristocracy of usefulness whose distinction is not exclusiveness but the widest sympathy, whose strength is not privilege but prodigal self-sacrifice. Let the estimate placed upon it by its members never fall beneath its great aims and achievements. Our part as its representatives is one of increasing loyalty and self-dignity. This duty lies before each of us and its fruits are within our own grasp as may be seen by the success of combined action of the profession whenever it has been attempted. In addition to Pandora's legacy to our race there is for our profession a large inheritance of charity as well as of faith in the progress of humanity and in its own destinies. These things that we see and know cannot much longer escape the notice of the people and of their leaders.

NOTES OF THREE CASES OF PERFORATED GASTRIC ULCER SHOWING COMPLICATIONS AFTER OPERATION,

ONE CASE ILLUSTRATING A NEW SURGICAL METHOD OF TREATING SEVERE RECURRENT HÆMORRHAGE FROM GASTRIC ULCERS.[1]

BY WILLOUGHBY FURNER, F.R.C.S. ENG., M.D. DURH.,
SURGEON TO THE SUSSEX COUNTY HOSPITAL.

THE chief or primary complications of gastric ulcers—viz., perforation, hæmorrhage, and subphrenic abscess—are also met with as complications following an apparently successful operation for the cure of perforated ulcers. After reading the notes of the cases I will offer for consideration in the course of my subsequent remarks two suggestions which have occurred to me—one for the treatment of severe recurrent hæmorrhage from gastric ulcers and the other for the adoption of additional precautions against the formation of retro-gastric subphrenic abscess after operation.

CASE 1.—The patient, a female, aged thirty-seven years, was suddenly seized whilst attending to her duties on May 24th, 1895, with severe abdominal pains. I saw her five hours later and found her somewhat recovered from collapse but with signs of general peritonitis. She said that she had suffered for a long time from indigestion and pain in the pit of the stomach. Vomiting, not especially soon after food, but at any time, began some weeks earlier. On opening the abdomen in the epigastric region a large abscess containing foul-smelling pus was found leading directly into the stomach. The wall of the abscess was also deficient at the lower part and it was evident that here there was a rupture into the general peritoneal cavity. A second incision was made above the pubes and both the abscess cavity and the general peritoneal cavity were thoroughly flushed. The abscess cavity was lightly packed with gauze drain and a drainage-tube was inserted above the pubes. The patient did well at first, the peritonitis subsiding, and at the end of seven days she was removed to the Sussex County Hospital where she remained for a fortnight longer, but the epigastric wound showed no signs of healing. All fluids which were swallowed ran out directly through the wound which became septic and the patient died on June 13th from exhaustion, three weeks from the date of rupture. I had left the town for a holiday on June 1st and I learnt the final details of the case on my return. The necropsy showed, as I was informed, the stomach to be contracted and adherent to the adjacent viscera, but there was no malignant disease. The patient died worn out with hectic and inability to retain food. I have since thought that I might have prolonged her life by performing the operation which I will describe later.

CASE 2.—The patient was a female, aged twenty-two years. She was admitted into the Sussex County Hospital on April 1st, 1898, with symptoms of ruptured gastric ulcer. She had suffered for about five years from anæmia and from pain after food referred chiefly to the cardiac end of the stomach. For some months she had been subject to vomiting after food but there was never any blood. On March 31st, when running upstairs before dinner, she was seized suddenly with severe pain in the left side of the abdomen and epigastrium. On admission, twenty-four hours later, she was still somewhat collapsed; the abdomen was distended and hard but there was no liver dulness. On opening the abdomen gas escaped but no stomach contents were visible in the peritoneal cavity. The stomach was empty, showing on the anterior surface of the lesser curvature close to the cardiac end an indurated surface about 3 cm. in diameter in the centre of which was a tear about 1 cm. in length. The stomach walls were folded over the induration and were stitched together by one row of Lembert's sutures. The peritoneal cavity was washed out with saline fluid and a gauze drain was left in the epigastric wound. The patient did well in spite of frequent vomiting during the first twenty-four hours till April 12th when the temperature rose to 101° F. There was no rigor and no pain and the respirations

[1] A paper read before the Brighton and Sussex Medico-Chirurgical Society on Nov. 3rd, 1898, with paragraphs added referring to cases simulating perforations and those on the technique of the operations.

Digitized by Google

were 32 per minute. Examination of the chest showed skodaic resonance over the left infra-clavicular region and dulness on the same side posteriorly over the base of the left lung. There was evidently a rapidly formed pleural effusion. On April 16th, the temperature being then 102°, the left pleural cavity was aspirated and 400 c.c. of clear fluid were withdrawn. After this the patient gradually improved and was discharged well with no pain after food on July 3rd. When seen two months later she had gained flesh and was well in all respects and showed no evidences of phthisis. The object in tapping the left chest at such an early date was to determine as soon as possible whether the fluid was purulent or not; if purulent there would have been stronger reason to suspect some irritation of the peritoneum, perhaps that of the lesser cavity which lies in relation with the posterior portion of the under surface of the diaphragm on the left side.

CASE 3.—The patient, a female, aged twenty-four years, was admitted into the Sussex County Hospital on Feb. 22nd, 1898, with symptoms of perforated gastric ulcer of four hours' duration. (She had been in the hospital for a few days in December, 1897, complaining of pain after food and nausea and she was then discharged feeling better.) For some time past the pain after food had been acute, coming on from half an hour to an hour after a meal, and was relieved by vomiting; there was also pain at night when the stomach was empty which was referred to the lower part of the sternum. There was no hæmatemesis. On Feb. 22nd after taking some bovril she was seized at once with acute pain in the epigastrium and with nausea but there was no vomiting. The patient was operated upon at 8.30 P.M., six and a half hours after the commencement of the symptoms. Perforation was found on the anterior surface of the lesser curvature about 2½ cm. from the pylorus. The peritoneal cavity contained gaseous and other contents of the stomach. The ulcer was closed by one row of Lembert's sutures and the peritoneal cavity was flushed with saline fluid and drained through the second opening above the pubes. Rectal feeding was followed for three days; then in addition small quantities of fluid food were given by the mouth, but as pain and flatulence followed feedig by the rectum only was resumed till Feb. 28th. On March 1st careful feeding with small quantities of milk and barley water by the mouth was again tried. There was no pain or flatulence. The patient passed a large, loose, black stool on the night of the 2nd, another soon after with a returned nutrient enema, and a third on the next morning. Melæna was absent on the 4th but it returned on the 5th. The patient was blanched and restless; nutrient injections were not retained and the rectum was full of black clot. Feeding by the mouth being out of the question and as it seemed too hazardous to trust to drugs to check the bleeding I decided to open the small intestine with the view of feeding the patient whilst resting the stomach. An incision through the abdominal muscles was made near the right semilunar line in order to avoid the sites of the epigastric and pubic incisions not yet healed and a thick-walled portion of small intestine, ascertained by drawing it out of the abdomen to be distant at least a metre from the ileo-cæcal valve and thought to be a good deal further, was opened and a small rubber tube was inserted; the intestine was fixed to the parietes. On the same evening the patient being very weak and restless after recovering from the anæsthetic was fed with 500 c.c. of peptonised milk through a tube in the intestine. A morphia suppository was administered per rectum. On the 6th the patient was much better. 500 c.c. of peptonised milk were given through the tube every four hours. She had a rigor during the night. On the morning of the 8th the temperature was 104° F. and the left parotid was swollen and tender; 25 c.c. of brandy were added occasionally to the food and 0·118 c.c. of solution of strychnine was given at each feeding. The morphia suppository was continued and a fomentation was applied to the parotid. On the 9th the patient was better. The temperature was 98·8° and the parotid was less swollen and not so painful. On the 12th feeding by the mouth in small quantities was re-commenced and feeding through the tube in the intestine was continued. The patient was beginning to gain flesh and she had no pain. On the 22nd she was fed entirely by the mouth; from this date onwards convalescence continued, but as the wound in the intestine left a small sinus which leaked this was closed by operation on July 6th and she left the hospital quite well with no pain after food on Sept. 9th. When seen six weeks later she was perfectly well.

Hæmorrhage after operation in any case similar to Case 3, excluding other causes of hæmorrhage, may proceed from the ulcer which perforated and has been closed; from injury during the operation to a previously healthy portion of the stomach; or from a second ulcer coexistent. Statistics [2] tell us that about 3 per cent. of cases of gastric ulcer die from hæmorrhage and that about 6½ per cent. of all cases perforate. Of those ulcers which perforate 36 per cent. are on the lesser curvature, 29 per cent. on the anterior surface, 9 per cent. on the pyloric end, 6 per cent. on the posterior surface, 5 per cent. on the cardiac end, and 2 per cent. on the middle of the stomach. In 13 per cent. there were two ulcers opposite to each other on the anterior and posterior surfaces of the stomach, the former being the site of the perforation while the latter was in most instances firmly adherent to the pancreas.

The above figures were collected prior to the time when operations for perforation were first performed. Quoting from more recent figures of gastric ulcers operated on at St. Mary's Hospital [3] Dr. Walter Broadbent tells us that out of 18 cases operated upon 3 cases had ulcers on the posterior wall as well, with their bases formed by the pancreas; 2 others had an ulcer on the posterior wall only through the mucous membrane; and in 1 case a perforation occurred in an ulcer on the posterior surface after the anterior one had been sewn up. In this list of all the cases which were operated upon one-third of the number had double ulcers. But whether a second ulcer is present or not, if grave symptoms such as perforation or hæmorrhage arise necessity for treatment is urgent whatever be the cause.

If there be a second perforation, surgically speaking, the abdomen can be reopened and the perforation closed with or without a gastro-jejunostomy. Before deciding to interfere surgically at all it is well to bear in mind the details of two cases in which serious symptoms of perforation are recorded, yet in which no second perforation was found. One of these cases [4] terminated fatally; no perforation existed and death was attributed to heart failure; in the other [5] the abdomen was reopened and the patient recovered. In each case the original ulcer was on the posterior wall of the stomach and the proximity of the solar plexus to the necessary adhesions may help to explain the symptoms.

Passing to the complication of hæmorrhage it will be remembered that in Case 3 life was threatened by profuse gastric hæmorrhage a few days after operation. Nutrient enemata could no longer be retained; the rectum was filled with clots and the small intestines (as proved subsequently during the second operation) also contained a quantity of black blood. Treatment by drugs seemed hopeless; nutriment was urgently required. Before deciding upon the best surgical proceeding in a case such as this after operation it may be well to consider the recently suggested surgical treatment performed in a few cases of hæmorrhage following gastric ulcer which have not perforated and have not therefore been subjected to operation. Mr. W. Rose,[6] writing on this subject in 1896, says: "Operations for hæmorrhage have not been frequent, indeed there are only two successful cases on record. Mikulicz performed one fatal operation and the two successful cases have occurred in the practice of Kuster." Dr. H. P. Hawkins [7] mentions Kuster as quoting four cases of excision of gastric ulcer where life was threatened by hæmorrhage, of which three were successful. These are the only cases of operation for non-perforated gastric ulcer accompanied by hæmorrhage which I have hitherto been able to find. Dr. Hawkins [8] quotes Leube as holding the opinion that operation should be performed not only where there are small and repeated hæmorrhages but also in a profuse hæmorrhage which is repeated. Leube reckons that in about 4 per cent. of all cases of non-perforated gastric ulcer surgical intervention is indicated.

The operations hitherto suggested or performed in non-perforated ulcer consist in opening the stomach and excising or cauterising the ulcer with or without pylorectomy and gastro-jejunostomy. I have found no record of any surgical measure for dealing with hæmorrhage following operation for perforated ulcer, but I submit that (*a*) temporary enterostomy such as was performed in Case 3 and might well

have been performed in Case 1 has this advantage, that when life is threatened by hæmorrhage from gastric ulcers, whether perforate or non-perforate, though enterostomy be not of itself a faultless or a curative measure, it offers nevertheless an alternative between a comparatively slight operation and a severe one and may enable us to sustain life during the critical period by feeding the patient while the stomach rests. The operation may be performed in non-perforated cases somewhat as follows. The abdominal incision is made with the centre level with the umbilicus or a little lower, 3 cm. from the middle line, 10 cm. in length, more or less, through the left rectus muscle. Push up the great omentum and the transverse colon. Slide the fingers along the lower surface of the transverse meso-colon to the spinal column and feel for the ligament of Treitz which is the guide to the commencement of the jejunum. Open the bowel about 1 metre or less from its commencement, avoiding risk of strangulation from taking a small loop, with a small sharp tenotomy knife so that a good sized Jacques catheter may be tightly grasped without leakage. Care should be taken to avoid a sharp spur by stitching the bowel above and below not too close to the opening or food may escape when feeding by the mouth is commenced. Adequate room should be allowed for the transverse colon in its normal position. The catheter passed into the rectal end of the jejunum may be stitched to the skin as well as to the Keith's dressing to avoid risk of displacement.

Reverting to cases already the subjects of operation such as Case 1 where food passed out immediately from the stomach through a gastro-cutaneous fistula or Case 3 where hæmorrhage occurred, few surgeons could confidently hope that patients in similar conditions would survive a second operation such as excision of the ulcer with or without gastro-jejunostomy. For these a temporary enterostomy as performed in Case 3 appears to be a reasonable surgical alternative to adopt. In such cases, however, choice of the site of incision may be limited owing to the presence of unhealed or septic wounds in the middle line. Where adhesions are absent at the site of incision a thick-walled portion of small intestine should be drawn out to ascertain that the future opening be not much within 1 metre either of the ileo-cæcal valve or of the commencement of the jejunum. If dense adhesions be present any guide (whether to the relative part of the small intestine to be opened or to its gastric or rectal extremity) might be entirely absent without employment of injudicious interference. The operator might then have to be content to open the most suitable portion of small gut presenting and to pass the tube a short distance only within its lumen. Under whatsoever condition the operation has been performed at a subsequent period the bowel should be released from its abdominal adhesions if pregnancy is likely to occur.

I come now to the consideration of retro-gastric subphrenic abscess as a complication following the operation, suggested but happily absent in Case 2. Some time ago the question was raised in this society[9] whether in cases where the cavity of the stomach could not be examined through the rent in a perforated ulcer on the anterior wall it might be well as a safeguard to ascertain the condition of the posterior wall through an opening in the omentum. I would go further than this and say that in all operations for perforated ulcer the lesser cavity of the peritoneum should be opened at the time of operation and for two important reasons. The first is, as suggested, for ascertaining the condition of the posterior surface of the stomach, because if we find that there is decided evidence of disease here, especially if implicating the pyloric end, after closing any ulcer we should more often go on to perform a gastro-jejunostomy than be content with only closing the ulcer. The second reason is that only by opening the lesser cavity and passing in the nozzle of the irrigator can this sac of the peritoneum be thoroughly flushed. The lesser cavity is well known to be a favourite site for subphrenic abscess when an ulcer affects the posterior wall of the stomach, but in the last fatal operation for perforated gastric ulcer which I saw death was due to an abscess in this situation, though there was only a single ulcer on the anterior wall which had perforated. Pus, as shown at the necropsy, had formed here, the foramen of Winslow was closed by adhesions; no recent general peritonitis existed, but both lungs were affected with extensive suppurative pleuro-pneumonia which was the immediate cause of death. The perforating ulcer on the anterior wall which had been closed by the operation was watertight and there was no other ulcer in the stomach, as I have said, to produce the subphrenic abscess. There can be no reasonable doubt, I think, that particles of the gastric contents had found their way from the greater cavity into the lesser, either before the operation or at the time of it, forced through the foramen of Winslow by the irrigating fluid.

Do not consider that I wish for a moment to advocate sponging in preference to irrigation for cleansing the peritoneum. I advocate irrigation but I contend that although the neglect to cleanse the lesser peritoneal cavity after operation for gastric ulcers has been often unattended with bad results this is a good fortune which should not be relied upon and that the lesser cavity of the peritoneum should be flushed as thoroughly as is the greater. Why has no notice been taken hitherto of the condition of the lesser cavity? Perhaps we may explain the omission in this way—that in many cases of general peritonitis following appendicitis, salpingitis, or other causes, effusion of pus or other septic fluid occurs in the lower part of the abdomen or about the pelvis and is not of great quantity; general peritonitis begins and the foramen of Winslow is closed by adhesions, thus shutting off the lesser cavity, just as we find in the converse condition when gradual leakage into the lesser cavity follows a gastric ulcer on the posterior wall general peritonitis does not ensue because the foramen closes. But in the case of a perforated anterior gastric ulcer the gastric contents have only to trickle round the right free border of the lesser omentum and both the greater and the lesser peritoneal cavities are practically simultaneously soiled. The lesser cavity of the peritoneum can be opened either through the layers of the great omentum or of the transverse meso-colon, preferably through the former. Division of the lesser omentum in part, though desirable sometimes when dealing with ulcers on the lesser curvature, does not give such convenient access to the lesser cavity.

Brighton.

TWO CASES OF CÆSAREAN SECTION.

BY JAMES BRAITHWAITE, M.D. LOND., M.R.C.S. ENG.,
OBSTETRIC PHYSICIAN AND SURGEON TO THE LEEDS GENERAL INFIRMARY; EDITOR OF THE "RETROSPECT OF MEDICINE," ETC.

CASE 1.—In May, 1897, I was called upon to operate in a case of pregnancy at full term in which the pelvis was blocked by an ovarian tumour so that delivery was impossible. Labour was threatening but it had not actually commenced. When the peritoneal cavity was opened the uterus was seen to be of a darkish blue colour, probably owing to the placenta having its attachment anteriorly. The uterus was rapidly opened by a scalpel which at the same time divided the placenta; the incision, however, was completed by the use of strong scissors. The hæmorrhage was very great but was controlled by pressure with the fingers by Mr. Knaggs who ably assisted me both in this case and in the second case and to whom I must tender my grateful thanks. The child was brought out by the head and the membranes and placenta were brought out immediately afterwards. The time from the commencement of the incision to the complete emptying of the uterus would not be more than five minutes. The finger was passed through the cervical canal which was found to be sufficiently open for drainage purposes. A sponge wrung out of hot boric lotion was put into the uterine cavity and one or two very large ones (also hot) were placed around and pressed upon the uterus which was now lifted out through the abdominal wound. No elastic ligature was used around the neck of the uterus. The wound in the uterine wall was closed by silkworm-gut sutures placed deeply at ½ in. intervals. These just missed the internal surface of the uterus. As it was noticed that the peritoneum was extremely loose and moveable owing to its not contracting in the same way that a muscular organ is capable of doing it was sewn over by a continuous catgut ligature. The original silkworm-gut ligatures were thus completely buried. The ovarian tumour was then removed in the ordinary way. The child was living and I hear that it is at present in good health. The mother made an uninterrupted recovery.

CASE 2.—This patient I saw first with her medical attendant, Mr. Spong of Leeds, at her own home, but she

Digitized by Google

was removed to the Leeds General Infirmary soon afterwards as she had had threatenings of labour. As in the previous case the pelvis was blocked with an ovarian tumour which so far as could be made out did not extend upwards into the abdomen. The cervix which was high up above the pubes could only be reached with difficulty. The fundus uteri was felt about 3 in. above the umbilicus and the patient was probably about seven months pregnant. She was kept in bed or sitting up in the ward for six weeks as there were no urgent symptoms of any kind and I thought it better to wait till the child was more likely to live. It was found, however, that the ovarian tumour was growing more quickly than the uterus and at the beginning of September, 1898, the upper edge could be felt above the fundus uteri. The pelvis, however, was completely blocked as before. It was therefore decided to operate at once. This was done on Sept. 6th. The operation closely resembled that described in Case 1 except that the placenta was attached to the upper and posterior part of the uterus and was not cut into by the incision. In this case as in the other a pair of very strong scissors was used to divide the uterine wall after it had been opened sufficiently by a scalpel to allow of this operation. I think this plan is better than a scalpel and director, as the uterus is more rapidly opened and the operator is less likely to injure the child. The child was found to present with its right shoulder and it was removed shoulder first. The placenta and membranes came out with it as the membranes accidentally caught on the child. The wound in this case was closed with 2 to the inch green chromic catgut. This catgut is very strong and I believe it is not absorbed so rapidly as the ordinary yellow catgut. In order to ensure proper adaptation of the sides of the wound the first suture was of course placed in the middle. The ovarian tumour was then removed. As in Case 1 I sewed the peritoneum over the uterine sutures. The patient made an uninterrupted recovery. The child, who was not quite at full term, unfortunately died in about twenty-four hours from atelectasis or non-expansion of the lungs.

It is difficult to make any remarks upon this operation which would be new as so much has been written upon the subject. It is, however, probably the most fascinating and interesting operation in surgery. The dangerous condition of the patient, the impossibility of relief in any other way, the certainty of death if it is not done when, as in such cases as these, delivery in any other way is impossible, and lastly the complete triumph over disaster by removal of the child in this way, together with the rapidity of the process, present to the mind a tragedy ending, however, in a complete and successful issue. The history and literature of the operation which is one of great antiquity is full of tragedies. For instance, in the year 1647 the operation was done by a bull which gored a woman eight months advanced in her sixth pregnancy. An abdominal wound was made from one sacro-iliac spine to the other. The intestines fell out between the thighs and the uterus was torn open. During the process of washing the intestines a living child came out through the wound in the uterus. The patient, however, recovered without a bad symptom and was out of bed in a month. There are at least 6 cases reported in which the patient did the operation upon herself and 5 of these resulted in recovery. Probably the most interesting of these cases is the following an account of which I abbreviate from THE LANCET of May 22nd, 1886, where it is related in full and attested by two medical men of Viterbo in Italy. A peasant woman aged twenty-three years and unmarried was pregnant at full term. Having been much annoyed by the remarks which were made as to her condition she determined to end the matter summarily. With a common kitchen-knife, not too sharp, she opened her abdomen on the right side of the umbilicus and then cut into the uterus. She drew out the arm of the child and cut it off. She then pulled out the head and amputated it. She then was able to remove the rest of the body and also the placenta and membranes. She bound herself tightly round with a broad band, and having hidden the fœtus in a straw mattress she dressed and walked into Viterbo which was rather less than a mile from her house to visit a sister, with whom she breakfasted on bread and coffee and a cup of broth. She then walked about the town for some time in order, as she stated, to show herself and to put an end to the current talk about her pregnancy, and returned home at 10 A.M., having been on her feet for about five hours. Some time after this, when at home, she vomited and fainted. One of the two medical men whose names are attached to the narrative was sent for and he found nearly all the intestines outside the body, and he states that he believed them to have been outside for at least six hours. With the assistance of his colleague the intestines were carefully washed and replaced, a drainage-tube was put in and the abdominal wound was closed. It is not stated whether sutures were put into the uterine wound or not. The wound healed and the patient rapidly recovered. In a previous comment in an annotation in THE LANCET of May 8th, 1886, upon this incident, as reported in *La Gazzetta degli Ospedali*, it was remarked that the "fearless bravery" of the old Romans evidently still survives.

What has struck me more than anything else is the safety of the operation provided the patient is in a condition to bear it. Beyond exhaustion there is really nothing for her to die from except it be hæmorrhage or sepsis. The hæmorrhage is perfectly under control by nipping and at the same time everting the edges of the wound by the fingers. This is more easy because the bleeding does not come from the whole extent of the wound but from two or three points only. It is venous hæmorrhage at very low pressure and is arrested quite easily. Of course it is completely stopped when the wound is brought together. I think it is an improvement in the technique of the operation to close the upper end of the incision the last and just before putting in the last two sutures to syringe the uterus well out into the vagina so as to ensure that it is free from clots of blood. It is very important to place the sutures near together and not, as recommended by Saenger, at intervals of an inch or so with superficial sutures between. If green chromic catgut is used in tying the knots I think it is also important to pass the end through the loop twice in making the first half of the knot. A knot so made with catgut is secure, otherwise it is not secure. There was an interesting case recorded in the year 1885 in which the sutures in the uterus gave way from vomiting and a clot was forced from the uterus into the peritoneal cavity. Catgut was used but probably the knots were not made in the way mentioned. Active contraction of the uterus, it must be remembered, is not necessary to stop hæmorrhage as the condition known as retraction is sufficient. When a contracted womb relaxes it becomes in a state of retraction, in which condition hæmorrhage does not occur. It is only when the womb expands or opens that bleeding takes place.

It is a well-established rule that in ovarian tumour with pregnancy the tumour ought to be removed at once. Pregnancy by this plan will not be interfered with and will go on normally. It may be suggested that I ought to have followed this rule, but in neither case was it possible to do so as the pelvis was blocked by the tumour and the womb lay completely above and anterior to it. In the second case, as stated, towards the end it was found that the tumour extended higher behind the womb than was supposed, but when the abdomen was opened it could not be removed or even seen, as the womb lay entirely in front of it.

I have either actually attended, or seen in consultation, or been responsible for, between 11,000 and 12,000 cases of midwifery. This large number of cases is greatly accounted for by 600 cases a year on the average attended in the maternity department of the Leeds General Infirmary and it has only been necessary to do Cæsarean section twice. We have, however, escaped it in 3 cases by doing symphysiotomy when the conjugate diameter has been 2¾ in. or over. I am afraid, however, that even now craniotomy is done when symphysiotomy would suffice. This latter operation is very satisfactory, for of the 3 symphysiotomy cases all the mothers recovered, and 2 of the children lived.

Leeds.

THE "BLIND FLY" AND THE LOCUST IN THE EVOLUTION OF THE MALARIAL PARASITE.

BY ARTHUR DUNLEY-OWEN, B.SC., M.R.C.S. ENG., L.R.C.P. LOND.,
SURGEON TO THE BRITISH SOUTH AFRICA COMPANY.

IN a paper on Malaria published in THE LANCET of Sept. 24th, 1898, I stated that I had made cultivations of the malarial parasite. My attention has been drawn to the following paragraph in Manson's "Tropical Diseases" page 2, "Hitherto all attempts to cultivate the parasite ..... have failed." I only obtained Dr. Manson's book in October, and

Digitized by Google

when I wrote my article my general knowledge of the subject was from "Fagge's Medicine." It is possible, therefore, that a brief description of the experiments which led me to contribute my notes to THE LANCET may prove of interest.

Rhodesian farmers have often told me that by keeping horses in during certain hours they prevented them from falling victims to "horse-sickness," and on investigating the subject I found, as I have mentioned before, that they were correct in their statements. This led me to inquire what there was in the herbage or the soil which could produce "horse-sickness" and I made microscopical examinations of dew, grass, and soil, but without any discovery. I then tried to make cultivations in the usual way on potato and with glucose gelatin, but again with no satisfactory result. On examining the blood of a horse suffering from "horse-sickness" I found the red blood corpuscles occupied by an amœboid body containing a black substance which I took to be melanin and also multitudes of sporules free in the blood serum. I examined the blood from 4 horses in this way and saw the amœboid bodies containing pigment and the free sporules in 3 cases. I did not, however, then find any crescentic bodies. This result being so similar to that which obtains in malarial blood in man I thought "horse-sickness" might be an analogous disease and with the hope of proving it I made the following experiments:—

A. "*Blind fly*."—I caught a number of that species of Tabanus which has a large grey-striped body, greenish-yellow eyes, and entirely transparent wings. This is locally termed the "blind fly" and it feeds on blood. I kept these in a cage of mosquito netting and at different times made the following investigations: 1. I examined several of the "flies" and found ?-curved bacilli in one case. 2. I allowed four of the "flies" to bite me during a malarial attack from which I suffered and examined them at intervals. (*a*) Two hours afterwards sporules and pigmented cells were to be found in the stomach contents. (*b*) In twelve hours pigmented cells were found in the stomach walls; and (*c*) on the fifth day while examining a third specimen I found deposits of pigment in the stomach walls and sporules and crescentic bodies in (?) lymph channels of the fly. 3. I allowed several "blind flies" to bite healthy horses but nothing abnormal was found in the contents of the stomachs. 4. I allowed others to feed on a horse suffering from "horse-sickness." The stomach contents of both the healthy horses and the "sick" horse showed sporules and pigmented cells. In one instance I found crescentic bodies.

B. *Locusts*.—I made the following experiments at different times with Acridium purpuriferum or the migratory locust: 1. I found flagellated bodies in the stomachs in 3 per cent. of locusts taken in early morning from the wet grass. 2. On keeping similar locusts for twelve hours I found sporules and crescentic bodies in the stomach walls in 1 case out of 50 which were examined. I considered these analogous to the malarial parasite because they were similar to acknowledged forms as seen in human malarial blood; but I dare say my conjectures are wrong.

C.—I injected rats with blood from a horse with "horse sickness" and produced rigors, elevation of temperature, and other signs of fever. On examining the blood of these rats I found amœboid bodies containing pigment and sporules, and in some cases in blood taken at a later period I saw many crescentic bodies. Other rats injected with blood from healthy horses showed only slight elevations of temperature, due, I take it, to the act of injection, and on examination their blood proved normal in every instance. Rats injected with the stomach contents of a "blind fly" which had been fed on my own blood showed the characteristic plasmodia in their blood five days afterwards. Rats injected with the "juice" of locusts caught in early morning showed symptoms of fever, but only once in 12 cases was I able to detect plasmodia in their blood.

I now see that I was in error in considering the crescentic bodies to be "bacilli"; I thought these were the active factors in true malaria and that the amœboid bodies were phagocytic in function.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

A CASE OF INDURATIVE MEDIASTINO-PERICARDITIS IN A YOUNG INFANT.

(Under the care of Dr. J. H. SEQUEIRA.)

THE following case is an excellent example of a rare condition which has received but scanty recognition. The first case seems to have been described in 1854 by Griesinger and up to the present about twenty-five cases have been recorded. There is much uncertainty about their etiology though it is not improbable that many are associated with tubercle. It is possible also that some of these cases start from a septic mediastinitis. For the notes of the case we are indebted to Dr. J. Blumfeld, late senior resident medical officer.

A male infant, aged fifteen months, was admitted to the North-Eastern Hospital for Children on Oct. 1st, 1896, with the history that in August there had been an attack of bronchitis and in September swelling of the face and legs. The case was sent to hospital as one of meningitis owing to a peculiarity in the child's cry. On admission the infant was pale but otherwise apparently healthy; he cried constantly unless he was nursed but he did not appear to be in pain. The temperature was 99° F., the pulse was 80, regular, and of fair size, and the respirations were 20. The tongue was clean.

On examination of the chest the area of cardiac dulness was found to be enlarged upwards on the left side reaching to the upper border of the second intercostal space; it extended also beyond the middle line of the sternum except over the manubrium. The heart sounds were everywhere normal. There were no adventitious sounds or bronchial breathing and the movements of the chest were normal. The liver and spleen were not palpable below the ribs. There was no tenderness or rigidity of the abdomen and there was no evidence of fluid; the feet and legs felt cold and pitted slightly on pressure. The urine was of specific gravity 1015, acid, clear, and contained no albumin. The infant took his food and slept well. He usually sat up but while sleeping he lay on his back.

The patient's condition remained unchanged, except that on some days there was blueness of the lips and ears, until Nov. 3rd. There was then an obvious amount of fluid in the abdomen, the arms and legs were cold and blue, and the legs were considerably œdematous. There was no cardiac murmur and no albumin was present in the urine. Distension of the veins of the neck was noticed. On the 10th the edge of the liver was palpable 2½ in. below the costal arch and on the 23rd there was extreme ascites with much œdema of the abdominal wall. The urine contained phosphates and about one-eighth albumin. On the 30th there was much diarrhœa and on Dec. 2nd the infant died with all the symptoms of cardiac dilatation.

Necropsy.—A post-mortem examination was made fourteen hours after death. When the sternum was removed the mediastinal tissues were seen to be greatly thickened and adherent. The anterior mediastinal glands were enlarged and presented foci of caseation. The left lung was adherent to the chest-wall at the apex and over the posterior surface of the lower lobe was some thickened and adherent pleura. The pericardium was about three-quarters of an inch thick, fibrous, and adherent everywhere to the heart, and the fibrous tissue spread upwards around the great vessels. Firm adhesions united the pericardium with the thickened anterior and posterior mediastinal tissues. The left pleura was adherent to, but separable from, the pericardium. The valves of the heart were all healthy. Both ventricles were

Digitized by Google

dilated and hypertrophied. The pericardium was carefully examined for evidence of tubercle but with negative result. The abdomen contained four pints of ascitic fluid. The liver was large, "nutmeg," and on section fatty; the kidneys and spleen showed changes due to venous engorgement. The heart was shown at a meeting of the Pathological Society of London on Dec. 15th, 1896.

Remarks by Dr. BLUMFELD.—Cases of primary disease of the pericardium without valvular affection are not very common. For this reason and because of the unusually early age at which the disease appeared this case seems to be worthy of record. In 1895 Dr. Thomas Harris published a monograph containing accounts of his own cases of mediastino-pericarditis and all others recorded up till then. The youngest patient mentioned by him was a child two years of age so that the above case probably represents the earliest age at which the affection has as yet been known to be present. Dr. Harris distinguished three pathologically distinct classes of "chronic inflammatory conditions in relation to the pericardium and mediastinum." In the first of these there is "adherent pericardium with marked increase of fibrous tissue in the mediastinum not infrequently associated with caseous affection of the lymphatic glands of the mediastinum and with adhesion of the exterior of the pericardium to surrounding parts." These cases, following Kussmaul, he named indurative mediastino-pericarditis, and the above case seems to be an excellent illustration of the condition, occurring, however, at an unusually early age. Such cases are of interest clinically because of the difficulty in diagnosing the condition and pathologically because their etiology is so obscure. If they are regarded as rheumatic one is confronted with the absence of endocardial affection—an absence which, at any rate in children, is so rare in rheumatic heart affections as almost to negative the supposition. Moreover, besides the absence of endocarditis and of joint affection there is in many of these cases no history of any illness which could be regarded as an attack of acute pericarditis, the disease beginning insidiously and the first symptoms being those of the consequent cardiac dilatation or of dropsy. In the present case except an increased area of cardiac dulness and an occasional lividity of the extremities there was nothing for weeks to lead anyone to suspect any affection of the heart. Cases such as these differ on the one hand from cases of obviously tuberculous pericarditis with generally much other evidence of tubercle and on the other from the obviously rheumatic cases where there is endocarditis as well.

Medical Societies.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

THE third ordinary meeting of this society was held on Dec. 21st.

Professor CHIENE showed (1) a well-marked case of Coxa Vara occurring in a lad, sixteen years of age, said to have been a result of rickets, but much more likely to have been due to traumatism; and (2) Double Partial Dislocation of the Hip-joint occurring in a typically rachitic girl.

Dr. AFFLECK showed (1) two cases of Friedreich's Ataxia in brother and sister; and (2) an extremely well-marked case of Addison's Disease occurring in a young man, the mouth presenting so many dark patches that it resembled that of a dog. There was no pulmonary disease when he was first admitted to the infirmary, though there were some enlarged glands in the neck. Suprarenal gland extract was administered, but as alarming symptoms followed the treatment had to be stopped, after which he began to improve markedly and soon gained a stone in weight. His strength also improved remarkably. The pigmentation still remains as before however. In another earlier case which Dr. Affleck also treated by suprarenal gland extract similar collapse was noted and the patient ultimately died.

Mr. CAIRD showed:—1. A man, aged fifty-eight years, from whom he had removed a rectal carcinoma by a parasacral incision. The growth affected the anterior aspect of the rectum and the exploring finger could reach beyond it. An exploratory incision was first made in the middle line of the abdomen and the growth was then found to be perfectly localised. The operation for removal of the growth was done on Sept. 6th; the wound is now whole. The patient has no incontinence of fæces, has put on weight, and feels in perfect health. 2. A patient after Removal of the Appendix and of a Renal Calculus. This affection occurred in a young man, aged twenty-one years, who had suffered from repeated attacks of typhlitis along with lumbar pain. An incision was made in the abdominal wall and the appendix was found to enclose three masses of fæces which could not escape. It was also embedded in inflammatory lymph and was consequently removed. No improvement followed however; the lumbar pain was still severe and the urine contained albumin and red corpuscles, though there was no pain radiating to the bladder or the testes. The kidney was cut down upon from the lumbar region and a calculus of the size of the terminal phalanx was removed. Since the second operation the patient has been perfectly relieved.

Dr. MELVILLE DUNLOP showed (1) a child suffering from Congenital Double Athetosis due to Cerebral Atrophy; and (2) a boy in the Atrophic Stage of Pseudo-hypertrophic Paralysis.

Dr. JAMES exhibited:—1. A case of Scleroderma associated with Symptoms of Raynaud's Disease which was present in a man, aged thirty-four years. Fourteen months ago the right index finger became cold and numb and a small part sloughed off. The same happened with the other fingers. The left hand next became affected, also the feet, the nose, and the ears. Small sloughs also formed on these localities. The skin now became very hard, specially under the chin; that over the hands became so hard that he could scarcely move his fingers. The skin over the face, neck, and over the body generally became hide-bound. He had great difficulty in opening the jaw, protruding the tongue, or putting the head back. His spleen was enlarged and the thyroid diminished in size. Tactile impressions were not interfered with but those for temperature were. 2. A case of Angio-neurotic Œdema of the Tongue occurring in a girl.

In Dr. GIBSON'S absence Dr. GRAHAM BROWN showed (1) a woman suffering from Bulbar Paralysis; and (2) a man exhibiting signs of Pseudo-bulbar Paralysis.

Dr. JOHN THOMSON showed a child with Hemiatrophy of the Tongue.

Dr. GEORGE ELDER showed: 1. A boy, aged six years, who showed Congenital Hemiatrophy of the Face with Malformation of the Ear. The atrophy affected not only the lower but the upper part of the face as well. 2. A woman, aged thirty-four years, with Senile Chorea. Four years ago she had a fall and sustained a Colles's fracture of the left arm. Previously to this her health had been perfect. Movements began to show themselves in the right hand after the accident.

Dr. W. ALLAN JAMIESON showed: 1. A drawing from a case of Urticaria Pigmentosa occurring in a child a year old. 2. A Papulo-squamous Eruption, apparently Syphilitic, affecting the Palms, in a man, aged forty-six years. 3. A case of Psorospermosis Follicularis Vegetans (Darier's disease) in a boy, aged eleven years. The disease began a year ago as a small spot on the outer side of the arm and gradually spread. There were large fungating masses on the arm, thigh, and face. In its early stage it appeared as small papules resembling molluscum or lichen planus. The hypertrophy was seen chiefly about the hair follicles. The psorosperms found by Darier in this disease were absent in the present case. 4. The result of treatment in a case of Tylosis which was shown at the November meeting. 5. Case of Elephantiasis in a woman, aged forty-three years. Six years ago the left leg began to swell at the ankle. The swelling spread upwards towards the thigh and then the right leg was affected similarly. The features which the legs presented were those of elephantiasis. There were nodular prominences on the skin and dilatation of the lymphatic tissues. The filaria nocturnans had been found in the blood of patients in this country. The blood in this patient was carefully examined after 8 P.M. but no filaria were found.

Dr. HODSDON showed a girl, aged seventeen years, from whom he had removed a large Plexiform Neuromatous Tumour from the Right Axilla. The growth had lasted about nine years and was divided into lobules. On operation it was found to be adherent to the periosteum and the median nerve passed through the centre of the tumour. Several other nodules were present in the sheaths of the nerves and these were shelled out. Other neuromatous

Digitized by Google

growths were present in other parts of her body—as, for example, in the right palm. Several other spots were present in the skin.

The following specimens were also exhibited:—

Mr. WALLACE: (1) A Renal Calculus; (2) Kidneys with Calculi *in situ;* (3) Fibro-adenoma removed from the Prostate; (4) Portions of Prostate removed from 3 Cases by Suprapubic Cystotomy; (5) 4 Kidneys (3 tuberculous and 1 carcinomatous) removed by operation; (6) Dermoid Cyst from the Floor of the Mouth; (7) a Biliary Cyst removed by Cholecystotomy; and (8) Microscopic Specimens of Tumours and of Prostate.

Dr. LOGAN TURNER: A Skull showing unusual Development of Frontal Sinuses.

Dr. DOWDEN: (1) Specimen of Plexiform Neuroma; (2) Microscopic sections of the same; and (3) Specimens of Hydatids.

Mr. CATHCART: (1) Abdominal Aneurysm which caused difficulties in Diagnosis; and (2) Multiple Abscesses in the Brain of a man convalescent from empyema treated by operation.

Mr. CAIRD: Preparations and Drawing from an unsuccessful case of Enterectomy and Suture for Carcinoma.

Dr. WILLIAM ELDER: (1) The Heart and Intestine from a case of Dysentery with Ulcerative Endocarditis; (2) Brain showing Hæmorrhage into the Occipital Lobe; and (3) Brain from a case of Word Blindness; the area of softening involved the supra-marginal convolution and the angular gyrus, extending as far inwards as the posterior horn of the left lateral ventricle.

Mr. CATHCART: Improvements in the Microtome.

Mr. CAIRD: Needle-case for Sterilising Needles and Sutures.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Chronic Inversion of the Uterus.—Pelvi-abdominal Disease.—Ectopic Pregnancy.

A MEETING of this society was held on Dec. 14th, Dr. HALLIDAY CROOM, President, being in the chair.

The following specimens were exhibited:—

Dr. BREWIS: (1) An Ovarian Tumour and a Calcified Fibroid Tumour removed from a patient aged seventy-four years; (2) a Five Months Pregnant Uterus removed for Cancer of the Cervix; and (3) Specimens from Two Cases of Hysterectomy.

Dr. J. W. BALLANTYNE: (1) Frozen Sections of a Fœtus hardened in Formol; (2) Multilocular Ovarian Cyst; (3) Vulvar Epithelioma removed by the Thermo-cautery (no recurrence); (4) Twin Fœtus (and Placenta) showing the First Stage of Sympodia; and (5) Secundines from Cases of Placenta Prævia.

Dr. HAULTAIN: A Uterus successfully removed by Vaginal Hysterectomy for Deciduoma Malignum.

The PRESIDENT: (1) A Missed Abortion; (2) an Ovarian Tumour complicating Pregnancy; and (3) a Parovarian Cyst.

Dr. J. W. STRUTHERS read notes of a case of Chronic Inversion of the Uterus replaced by Manipulation after Posterior Colpotomy had been performed. The patient was thirty-eight years of age and when admitted to the hospital was suffering from menorrhagia and metrorrhagia Nineteen months previously she had been delivered of her eighth child. Labour was precipitate, the child being born on the floor. A medical man who was sent for removed the placenta without any difficulty and told the patient that her womb had come down. There was no shock or excessive hæmorrhage after the labour or during the puerperium. On admission a smooth, firm body of about the size of a hen's egg was found projecting through the cervix which was found to constrict the tumour slightly to the cervix; the diameter was about 1 in., lower down at its widest part it was about 1¼ in. No body of the uterus could be felt on bimanual examination. Attempts were made to reduce it under chloroform by hand and by Aveling's repositor but without result. Slow pressure by the repositor was also tried but failed. The vagina was douched and packed with iodoform gauze for eight days and then Dr. Berry Hart operated by incising the posterior wall of the vagina for 1¼ in. Two fingers were introduced through this and passed down into the infundibulum uteri. No adhesions were found. The fingers of the right hand manipulated the body of the uterus and the left fingers fixed the uterus and also kept the cervix stretched as contraction otherwise prevented the reposition. This gradually effected the replacement. A silk stitch was inserted through the lips of the cervix to prevent any tendency to recurrence and the vaginal incision was also united with silk. The patient did well.

Dr. HAULTAIN gave a Retrospect of a First Series of 110 Abdominal Sections for Pelvi-Abdominal Disease with 2 deaths. The table included 35 ovariotomies with no deaths; their ages varied from twenty-one to eighty-one years. The largest tumour weighed 83 lb. and after recovery the patient's weight was 84 lb., only 1 lb. more than the tumour. Of simple pedunculated cysts there were 18 unilateral and 3 bilateral; of simple sessile cysts 3 were abdominal and 4 were sub-peritoneal pelvic. There were 2 bilateral papillomata and 1 unilateral; also 2 fibromata, 1 oöphoroma, and 1 dermoid. With 2 of the solid tumours of the ovary ascites was present; with the cellular oöphoroma no peritoneal effusion was present. The presence of ascitic fluid with these solid tumours of the ovary was a matter of considerable interest and was difficult to account for especially when one considered that similar tumours of the uterus were not equally complicated. It was possibly due to the fact that the uterine fibroids obtained their nutriment from their capsule in which the inoculation was at all times easy, while the solid ovarian was nourished entirely by means of vessels which entered within a limited area and ramified through its structure. It would thus be evident that in dense fibrous growths the blood-return would become gradually impeded and a serous intra-peritoneal effusion result. As they were often of comparatively small size and of slow growth they would often remain undetected were it not for the accompanying ascites. The fungating papillomata were associated with extensive ascites; there had been no recurrence after removal in one of these patients, in this case no evidence of infection of the peritoneum could be found. Dr. Haultain's list of operations included 2 broad ligaments cysts and 3 hysterectomies. In the latter case the stump was treated by the intra-peritoneal method after ligature of the uterine arteries. There were also 3 myomectomies. In 2 patients there were mixed tumours: 1 had an ovarian tumour on the left side and a broad ligament cyst on the right; the other patient had a large ovarian cyst and a parovarian on the right side, numerous fibro-myomata of the uterus, and a large broad ligament cyst on the left. Extra-uterine gestation occurred in 5 cases of the series. 3 of these showed that the source of the bleeding was through the patent abdominal extremity of the tube. From a close examination of the specimens after removal it would seem that in the majority of the cases separation of the ovum with necessary bleeding was the primary factor in the so-called rupture. This bleeding might take place through the ostium and also might be the source of the irregular uterine discharge with which ectopic gestation was so constantly associated at the time of so-called rupture. One of the extra-uterine operations was rendered very difficult by the remains of an old appendicitis. Dr. Haultain performed ventro-fixation five times, twice for enlarged, congested, and fixed retroflexed uteri which gave rise to marked symptoms unrelieved by other treatment. In 2 cases of prolapse the result was satisfactory; in a third a secondary colporrhaphy had to be performed to rectify a pronounced rectocele. In performing the operation he stripped off the parietal peritoneum from the edges of the abdominal wound and fixed the fundus to the extra-peritoneal tissue by means of silkworm gut sutures which included the skin and recti muscles as well as penetrated the anterior uterine wall. The Porro-Cæsarean operation was performed on one patient. She was a dwarf and in the second stage of labour. The pains were violent and uncontrolled by anæsthesia. The conjugata vera measured 2 in. The stump was treated extra-peritoneally and was secured by the elastic tube. The child was saved and the mother recovered. Suprapubic cystotomy was performed in 3 cases for new growths in the bladder, all papillomatous and freely hæmorrhagic. The ages of the patients were seventeen, fifty-one, and fifty-two years. The suprapubic method was preferable to urethral dilatation or vaginal cystotomy. Urethral drainage was more comfortable to the patient than through the wound. There were 10 cases of exploratory incision with 1 death. These included operations for malignant disease of the peritoneum, tuberculous infiltration for adherent ovaries, to fix up prolapsed ovaries, and to release an adherent pedicle. The fatal case was an

Digitized by Google

exploratory incision on a post-uterine tumour which was causing pressure symptoms. It was found to be a sub-serous cervical fibroid and as the vaginal route for its removal seemed preferable the abdominal wound was closed. The patient succumbed from acute septic peritonitis on the third day before the second operation was undertaken. The appendages were removed in 41 cases. 2 of these were for dysmenorrhœa, all other treatment proving of no avail. This operation was also undertaken on a patient with a monthly mental aberration that she was harbouring a man inside her; the delusion was cured for a few months and afterwards returned. 4 cases of fibro-myomata were treated in this way; 3 with excellent results; 1 is unimproved. In 23 cases this operation was performed for diseased ovaries or matted appendages. There were also 3 cases of hæmatosalpinx, 1 of hydrosalpinx, 6 of pyosalpinx, and 1 of tubercle of the tubes. The second death in the list was after operation on a pyosalpinx. As regards technique Dr. Haultain carried out asepsis in hospital practice but in private practice used antiseptic methods. Hæmorrhage should be fully controlled, especially by ligaturing the main sources of the blood-supply, before proceeding to free adherent tumours. Drainage was not used unless excessive hæmorrhage was feared and the vaginal route was preferred. In suturing the abdominal wound all the layers were included with silkworm-gut sutures. A nutrient enema was always given after the operation and was repeated every few hours if sickness was present. Light food was given whenever the stomach could retain it. Thirst was relieved by large saline enemata. As complications in this series he had had a case of double suppurative parotitis. In one case a pair of forceps had been accidently left in the peritoneum. The patient's temperature was irregular for twenty days after the operation, the next three days it was practically normal, but she was distinctly and rapidly failing. At the second operation the forceps were found embedded in plastic effusion and with difficulty were removed; the patient recovered slowly.—The PRESIDENT, Professor SIMPSON, Dr. HART, Dr. BREWIS, and Dr. MILNE MURRAY made remarks on the paper.

Dr. HAIG FERGUSON read a paper on Repeated Ectopic Pregnancy in the same patient with an account of a case where Two Gestation Sacs (one a Lithopædion) were successfully removed from either side at one operation. In surveying the published cases he found that in about 5 per cent. of all extra-uterine cases both tubes had been involved at the same time or at intervals more or less prolonged. The shortest interval was six weeks and the longest was five years. Dr. Ferguson's patient, after bearing 2 children, had menorrhœa for 4 months. She was then suddenly seized with pain on the right side with shivering and was confined to bed for many weeks. After 4 years her menses again stopped. After 2 months she suffered from pelvic pain and retention of urine. On examination a fluctuating swelling was found of about the size of a goose's egg on the left side of the uterus which was enlarged and pushed to the right. On the other side of the pelvis a hard, irregular body was found. A small piece of decidual membrane was passed from the uterus after the examination. On operating a tubal pregnancy with the ovary was removed from the left side. It had ruptured into the broad ligament, fresh blood-clot being found there. On the right side the tube was dilated to the size of the small intestine and was filled with serum. Attached to it was a sac which was found to contain the bones of a four months fœtus. This lithopædion sac lay in the peritoneal cavity attached to the tube by a narrow fibrous pedicle and looked as if it had been originally extruded through the peritoneal covering of the tube. The right ovary was cystic and was removed at the same time. The patient made an uneventful recovery. Appended to the paper was a list of all the references to the literature on the subject.—Dr. CROOM, Professor SIMPSON, Dr. HART, and Dr. HAULTAIN took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Acute Hæmorrhagic Ascites.—Medical Folk-lore.

A MEETING of this section was held on Nov. 18th, 1898, Dr. J. W. MOORE, the President, being in the chair.

Dr. FINNY described a case of Ascites in a man, aged forty-two years, which proved fatal in three months from its earliest onset and for which paracentesis was required five times in the last three weeks, six and a half gallons of fluid being removed by simple drainage. The fluid from first to last was like blood in colour and on standing deposited a soft deep-stained sediment forming one-eighth or one-tenth of the volume. The patient was apparently up to the last fortnight of his life a healthy, well-nourished man, of a good fresh colour, a bright disposition, and of very active habits. At the post-mortem examination the liver was found to be healthy. The intestines were pressed to the right side by an enormous thickening of the transverse mesocolon and omentum and by a soft growth which filled up the whole of the left side of the abdomen and was in parts 2 in. thick and which readily broke down on handling, blood oozing from every part.—Dr. PURSER pronounced the neoplasm to be sarcomatous.

Dr. J. KNOTT read a paper on a Country Herbalist's Cure for the King's Evil. The details had been procured from a sexton in the west of Ireland. The cure was carried out in three stages: (1) the "sore" was dressed with a preparation of the leaves of the cuckoo sorrel; (2) it was then dressed with a preparation of the root of the sweet meadow; and (3) the healing was completed under a plaster compounded of bees' wax, sheep suet, yelk of egg, and first flour. Dr. Knott had found on looking into the literature of herbal simples that both the plants employed in this rural remedy had enjoyed a high reputation during the ages in which such remedies were specially prized. The treatment of scrofulous ulcers by the application of these herbs is mentioned by Dr. Thomas Beddoes and the account of it was quoted from this writer by Dr. T. M. Winterbottom who compares it with a very similar treatment of scrofulous sores which he had found in general practice among the aboriginal African natives about Bassa, on the Grain Coast. Lengthy quotations were given from a number of authorities, showing the extensive employment of these remedies in the herbals and pharmacologies of past ages.—Dr. COX said that Dr. Knott had omitted to refer to a book written by Keogh, a distinguished graduate of Trinity College in the last century. There was formerly in Ireland much medical literature and even at the present day a large amount existed not only in the Dublin museums but also in the British Museum. They had to thank men like Whitely Stokes for having enlightened the world as to the position of Irish learning bearing on this as on many other subjects.—Dr. KNOTT, in reply, said he had, as Dr. Cox had mentioned, omitted to mention the name of Keogh in connexion with the extract which he had made. He hoped that some day someone, under the auspices of the Royal Academy of Medicine in Ireland, would give a translation of the Irish writers on medicine. He considered that there was one man especially capable of doing so and that was Dr. Cox himself.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on Dec. 21st, Mr. Alexander Miller, President, being in the chair.—Dr. Edgar showed: (1) Placenta Duplex from a case of Placenta Prævia Centralis; (2) Retroflexed Fœtus; (3) Anencephalic Embryo of four weeks; and (4) Exencephalic Embryo of four weeks.—The President gave an interesting address on Twenty Years' Obstetric Practice. This embraced a consideration of 1000 cases. Of the many complications he referred to probably the most interesting was the one of acute inversion of the uterus. This was produced by the woman in attendance dragging on the cord. Mr. Miller found no difficulty in reducing with his hand the inversion which was complete.

PUBLIC ABATTOIRS FOR BRISTOL.—At the meeting of the Bristol Health Committee held on Dec. 20th there was a discussion on the question of public abattoirs which were strongly recommended in a report submitted some months ago by the medical officer of health (Dr. D. S. Davies). Apparently, however, the local tradesmen have some prejudice against municipal slaughter-houses and consequently, on the suggestion of the chairman, it was decided to have a conference between the committee and representative traders.

Reviews and Notices of Books.

A Text-book of Diseases of the Nose and Throat. By FRANCKE HUNTINGTON BOSWORTH, A.M., M.D., Professor of Diseases of the Throat in Bellevue Hospital Medical College, New York, &c. Third edition. Illustrated with 186 engravings and 7 coloured plates. London: Baillière, Tindall, and Cox. 1897. Pp. 814.

DR. BOSWORTH'S larger work in two volumes is well-known as a valuable treatise on the nose and throat, but it was—not unreasonably—considered that it was too voluminous for the ordinary student and general practitioner; he has therefore had the work cut down to the size of the present volume. This has been done by Dr. A. R. Schroeder. The result is very satisfactory for we find a careful account of the diseases of these important regions of the body comprised within one volume of moderate size, though it still occupies more than 800 pages. A good account is given of the methods of examining the upper air passages and the author considers that the direct rays of the sun form by far the best source of illumination and that they should always be used where available, especially in the first examination of the case. In his opinion the incandescent electric light offers no advantages over the ordinary gas-jet or paraffin lamp. The anatomy of the nose and nasal cavities is fully described and an account is given of their functions. In the treatment of hypertrophic rhinitis the author prefers chromic acid to the galvano-cautery, as he considers that the latter is a cumbrous method for destroying merely a small portion of tissue. Dr. Bosworth, in agreement with many rhinologists, does not think that advanced cases of atropic rhinitis can ever be really cured though the annoying symptoms may be removed. The diseases of the cavities opening into the nose receive full consideration. In the account of the external surgery of the nose is given a large series of wood-cuts (42 in all) illustrating the skin incisions and the extent to which the bones are sawn in the various operations; they will serve to make clear to the reader what is often very difficult to understand from a description only. The next section is devoted to the diseases of the fauces. It is well written, and we need only remark that "croupous tonsillitis" is not a satisfactory synonym for acute follicular tonsillitis. The account of the larynx is good and quite full enough for all practical purposes. The last section describes the external surgery of the throat and contains accounts of pharyngotomy, thyrotomy, tracheotomy, and extirpation of the larynx. The illustrations throughout the book are numerous and the coloured plates are good. From a careful examination of the work we can recommend it with confidence to all who wish for a fuller account of the diseases of these regions than can be found in the ordinary text-books on surgery.

Disinfection and Disinfectants. By SAMUEL RIDEAL, D.Sc. Second edition. London: The Sanitary Publishing Co., Limited. 1898. Price 12*s.* 6*d.*

DR. RIDEAL has done a good service in the interests of sanitation by having written a reliable work dealing with the merits and demerits of the processes of disinfection in vogue and of the various chemical agents employed therein. We venture to maintain that the Government should provide some means of control over the various preparations placed on the market as disinfectants, since many of them are quite inert, exerting little or no bactericidal action, and thus deluding the public into the belief of security against infection. The work before us affords a useful means of discriminating between the active agents and those which are worse than useless. Moreover, in many instances it records the comparative bactericidal power of disinfectant substances. The list of these is now almost interminable, new ones said to eclipse previously existent ones in regard to bactericidal power being added almost day by day. Some idea of this number may be gained from the very interesting and instructive chapters of Dr. Rideal's book. Of a total of fifteen chapters no less than eight are devoted to chemical disinfectants which are classified as follows: the Non-Metallic Elements and their Derivatives (Chapters IV. and V.), Metallic Salts (Chapters VI. and VII.), Organic Substances (Chapters VIII., IX., and X.), and Compounds related to the Alcohols (Chapter XI.). The remaining chapters are devoted to the general principles of disinfection, mechanical disinfection, disinfection by heat, personal disinfection, the preservation of food, legal statutes and regulations, and lastly methods (bacteriological and chemical) of analysis.

The author freely recognises the assistance which a reference to the bibliography on the subject has afforded him and our own columns are frequently referred to in connexion both with practical inquiries which we have ourselves undertaken and the opinions and results expressed and contained in papers communicated to THE LANCET from time to time. It must have cost considerable time and labour in thus bringing together the gist of the literature which on this special subject is so very widespread. This alone merits a word of praise. But more than that, the book supplies in collective form just that information of which our medical officers of health and others concerned in sanitary organisation and administration are daily in search. It contains practical particulars and directions, and throws light upon the composition, character, and value (bactericidally) of many proprietary preparations and the bactericidal worth also of substances which are more familiar. In short, Dr. Rideal's book is a contribution of great importance to medical men, for it should very materially help them when they are confronted with the important question, as is so often the case, as to the best means of carrying out disinfection on the small scale and on the large.

LIBRARY TABLE.

A Short Manual of Analytical Chemistry. By JOHN MUTER, Ph.D., F.R.S.E., F.I.C., F.C.S. Eighth edition. Illustrated. London: Baillière, Tindall, and Cox. 1898. Price 6*s.* 6*d.*—There is an abundance of text-books on analytical chemistry, but Dr. Muter's manual is sharply distinguished from the bulk of these by not being confined to a special course or being written on the lines of examinational requirements. To some extent, however, the work has been written for those undergoing special study. Thus there are several chapters in it which are useful to medical and to pharmaceutical students. The sections on the qualitative detection of alkaloids and on certain organic bodies used in medicine with a general sketch of toxicological procedure and special processes for the analysis of drugs, urine, and urinary calculi may be quoted as examples. But the book, considering its size, is remarkably comprehensive in the treatment of the broad subject of analysis. The earlier portions are devoted to the ordinary methods of qualitative analysis and the detection of unknown salts, metals, acids, &c. In later sections we find chapters on volumetric and gravimetric quantitative analysis applied to the same class of substances. Then follows ultimate organic analysis until in Chapter X. the analysis of water, air, and food is described and the processes are in accordance with our present knowledge. The work is original in its plan and should serve as an excellent guide to those who are taking analytical chemistry as a study. Though a comparatively small volume it gives

Digitized by Google

an excellent idea of the wideness of the application of chemical analysis in the sciences and arts.

Twenty-two Years' Experience in the Treatment of Cancerous and other Tumours, with an Introduction on the Increasing Prevalence of Cancer and the Remedy for that Disease. By HERBERT SNOW, M.D. Lond., Surgeon to the Cancer Hospital. London: Baillière, Tindall and Cox. 1898. 8vo. Pp. 191. Price 5*s.*—In this book Dr. Snow generally uses the word "cancer" in its popular sense as synonymous with malignant disease, though occasionally he gives it a less extensive signification. The introduction contains remarks "on the increasing prevalence of cancer and the true remedy for that disease"; and we are told that "this huge aggregate of yearly deaths signifies nothing less than imperfect acquaintance with technique by most of those who are entrusted with cancer operations." This is a grave accusation and should not have been made, for its lack of foundation is known to all those who are acquainted with the facts. Dr. Snow finds fault with the ordinary pathological ideas with regard to malignant disease, rejects the common classification, and proposes one which is certainly more complex. At the present time, when the association between surgery and pathology is so intimate, it is almost incomprehensible that an author should write the following sentence, which we find on page 33: "To the existing practical divorce between the two branches [surgery and pathology], to the confused state of the latter, to the defective way in which it is usually taught, to the ultra-conservative instincts of the societies devoted to its culture, must be ascribed a large share in the progressive increase of cancer mortality." As to etiology, Dr. Snow thinks that "some palpable derangement or perturbation of the central nervous system is the all but invariable precursor of the most prevalent form of cancer," though he does not think that sarcoma has any such origin. In the medicinal treatment of cancer the author extols the value of morphine and cocaine, but the utility of these drugs is already well known to every surgeon. We are told that the only drugs which can arrest the career of cancer are "neurotics"; this is decidedly a novel use of the word and it is clearly not a printer's error for it is repeated. On page 93 it is said that when opium is smoked like tobacco all the essential principles are burnt up and none inhaled. This statement is not in accordance with the experience of many. Rodent ulcer is said to be "easily" eradicated; surely the adverb is rather misapplied. Dr. Snow insists much on marrow infection in cancer; undoubtedly it frequently occurs but it does not deserve to be given the important position assigned to it by the author in the tendency to recurrence and secondary infection exhibited by malignant disease. There are many ideas of value in the book but throughout is manifested a tendency by the writer to magnify his own work, knowledge, and power and to belittle the skill and achievements of others.

The Deformities of the Fingers and Toes. By WILLIAM ANDERSON, F.R.C.S. Eng., Surgeon to St. Thomas's Hospital, Examiner in Surgery at the University of London and the Royal College of Surgeons of England, &c. London: J. & A. Churchill. 1897. Pp. 150. Price 6*s.*—In 1891 Mr. Anderson delivered a course of Hunterian Lectures on the Deformities of Fingers and Toes and this volume contains the substance of those lectures, revised and brought up to date and augmented by a chapter on the Congenital Deformities of the Hands and Feet. The lectures were much appreciated when they were delivered and were well worthy of this reprint. The first section is devoted chiefly to a very important subject—namely, Dupuytren's Contraction of the Fingers. The first description of this condition was given in 1820 by Sir Astley Cooper who recognised the non-tendinous origin of the disease, but it was more fully described by Dupuytren in 1821, so that his name has ever since been attached to the disease. As to its frequency Mr. Anderson examined 2600 adults in several London infirmaries and found 33 cases, or 1·27 per cent.; but in 800 children not even one case was found. From the author's own experience he is not inclined to attribute much effect in the etiology of the disease to neurotic or gouty predispositions, but he admits that as most of his cases were infirmary patients these constitutional states would not have been so likely to be present as in other classes of the community. In one case by a bacteriological examination the presence of a micrococcus was demonstrated, but obviously no satisfactory opinion can be based on a single case. As to treatment, Mr. Anderson thinks that in mild cases non-operative measures may be sufficient and he considers that, although Adams's subcutaneous method may be sufficient in some cases, yet a plastic operation gives better results. Few would imagine that any danger could arise from Dupuytren's contraction, but Mr. Anderson relates a case in which a gentleman caught his contracted finger in the door-handle of a railway carriage with the result that he was only saved from severe injury by throwing his other arm round a pillar and so arresting his involuntary flight, but the sudden stoppage tore open the contracted digit. Hammer toe is well described and the tendency which this deformity exhibits to be transmitted by heredity is illustrated by a pedigree which shows its appearance in four generations. The author does not consider that short boots have anything to do with the causation of this condition. Resection of the joint (the articular ends of both bones being removed) is recommended as the most eligible operation, and the relief is immediate and permanent. Hallux flexus has not received as much general recognition as hammer toe; a good account is given of it and of hallux valgus and varus. The final chapter, on Congenital Deformity of the Hands and Feet, is not the least interesting in the volume.

New Inventions.

THE "ASSOCIATION" VACCINATOR.

WE have received from the Association for the Supply of Pure Vaccine Lymph, 12, Pall Mall East, one of their "Association" vaccinators, for which it is claimed that by its use the cuticle may be removed without the risk of drawing blood. This is a desirable property in an instrument employed for the insertion of lymph because the oozing of blood during the operation is not only unnecessary but it dilutes the lymph, interferes with its absorption, and is occasionally somewhat of a deterrent to mothers of infants. The vaccinator consists of three parts—a hollow handle of polished metal 3¾ in. in length, a set of four parallel needles fixed permanently to a needle-piece or mount which screws into the handle, and, lastly, a metal cap to cover

the needles when not in use. The illustration shows the needles and needle-piece, full size, screwed into the handle and covered by the cap represented by the dotted line. It will be seen that only about 1½ in. of the handle appears in the illustration. The hollow handle is convenient for carrying tubes and a small hole drilled right through the needle-piece, as shown in the figure, is useful for breaking off their sealed ends. The needles are sterilised by boiling, since, if held in a flame, they will be softened and easily bent. Their shape is the special feature of the instrument, for they are not brought to a sharp point but have their ends quite flat. The price of the vaccinator is 5*s.*

THE LANCET.

LONDON: SATURDAY, DECEMBER 31, 1898.

THE ANNUS MEDICUS 1898.

Medicine.

THE most important medical event of the year has probably been the passing of the Vaccination Act. This subject is dealt with at length in another part of our present issue (see p. 1790).

The proposal to establish a national crusade against tuberculosis has met with a large amount of support. The meeting held at Marlborough House under the Presidency of H.R.H. the PRINCE of WALES on Dec. 20th was indicative of the widespread interest which the movement has aroused. The presence of prominent statesmen and other well-known personages as well as many leaders of the medical profession augured well for the success of the association. But with another aspect of the case the National Association for the Prevention of Consumption and Other Forms of Tuberculosis promises to work much good for the general community—namely, in agitating for reforms in our food-supplies. Sir RICHARD THORNE in delivering the Harben Lectures chose as his subject the Administrative Control of Tuberculosis. He expressed the view that the source of danger from the meat-supply had been exaggerated, but that the remedy for such risk as existed lay in the abolition of private slaughter-houses and the provision of public ones in which a uniform system of inspection and a uniform standard for condemnation would be observed. The danger of the milk-supply to man and especially to the infant population he considered to be one of real gravity, and the loss of child-life due to tuberculosis in milch-cows was appalling. He laid great stress on the adequate ventilation of cowsheds and advocated frequent and systematic inspection of cowsheds and dairies by expert officials. The value of the open-air treatment of pulmonary tuberculosis is rapidly becoming recognised and promises to be the principal treatment of this disease in the future. In this country there are obvious difficulties with regard to its general adoption, but Dr. BURTON-FANNING and Dr. POTT have done much to encourage further trials in suitable districts.

During the past year there have not been so many bacteriological discoveries to record as in previous years. Dr. SIDNEY MARTIN in delivering the Croonian Lectures discussed generally the nature and action of the Poisons and Chemical Products formed by Pathogenic Bacteria and illustrated the subject by an original investigation of the pathogenic action and the chemical pathology of the bacillus of typhoid fever and two other bacilli closely related to it—namely, the bacillus enteritidis (GÄRTNER) and the bacillus coli communis. These lectures have added valuable information to our knowledge of the more precise action of these organisms. Investigations have been made by GRASSI, BASTIANELLI, and BIGNAMI in Italy and by Dr. PATRICK MANSON in this country which promise to have an important bearing on the prophylaxis of malaria. These observers maintain, and their contention is supported by experiments, that malaria may be contracted by means of mosquitoes. Their investigations are not yet complete and before definite statements can be made extensive observations will have to be carried out in other malarious districts than those in which experiments have already been conducted.

A full report on the Plague in India in 1896 by Mr. R. LATHOM, of the Indian Civil Service, has recently been published. It forms an excellent report of the epidemic and affords information of the greatest importance. It shows that the plague is no longer the inevitable scourge of former times. The malady remains a virulent and dangerous one but it has been found that careful nursing and healthy surroundings give the patients a chance of recovery greater than would have seemed possible during the epidemics of former days. The infection has been found to spread according to simple natural laws and can be fought by the prompt adoption of the measures dictated by science, common-sense, and experience. Sanitary and well-ventilated dwellings and cities containing ample space for their inmates are the conditions which render the spread of plague practically impossible. The bacillus of plague was first discovered by KITASATO and YERSIN in 1894. During the present epidemic the previous conclusions have been verified and the investigations into the bacteriology of the disease have been carried further by M. HAFFKINE, Professor HANKIN, and others.

Three fatal cases of plague occurring in Vienna caused much consternation, but fortunately, owing to the lessons learned from larger outbreaks, due precautions were taken and its spread was prevented. The facts are known to our readers but may be briefly recapitulated. For several months the members of the Austrian Commission who went to India for the purpose of studying plague in its clinical and bacteriological aspects had been continuing their investigations in the laboratories. In some manner an attendant who was engaged in looking after the inoculated animals contracted the disease and succumbed. Dr. MÜLLER who was in charge of him and two nurses who attended him also became affected and Dr. MÜLLER and one of the nurses died, but no further cases occurred. The sad occurrence emphasises the fact that where the organisms which cause this deadly disease are being experimented with, and, in fact, whenever they are present, whether accidentally or not, no precaution, either great or trifling, is to be neglected for the purpose of confining the organisms to the sphere allotted to them.

Dr. ROSE BRADFORD in the Goulstonian Lectures dwelt upon several points in the pathology of the kidneys. He detailed the results following partial nephrectomies (of varying degrees of severity) both on the composition of the urine and on the general metabolism of the body, and showed that whereas all partial nephrectomies increased the flow of urinary water only the more severe ones increased the excretion and production of urea. The effects following complete double nephrectomy were also considered and the lecturer explained his views as regards the nature of uræmia. He came to the conclusion (1) that uræmia cannot be held to

Digitized by Google

be due to simple retention and (2) that in kidney disease and after experimental lesions of the kidneys there is evidence of great tissue disintegration, and that it is more than probable that uræmia is dependent on this directly or indirectly.

Dr. HUGHLINGS JACKSON'S lecture on the Relations of Different Divisions of the Central Nervous System to One Another and to Parts of the Body showed the originality of thought and keen powers of observation for which the lecturer is well known. His observations on the various forms of epilepsy and allied conditions and the relations between the cerebral centres and nerve discharges will prove most valuable to those who are engaged in the study of these conditions.

In the Lumleian Lectures Sir R. DOUGLAS POWELL considered the Principles which Govern Treatment in Diseases and Disorders of the Heart. Especially interesting were his remarks on the cardio-vascular neuroses. He defined "cardio-vascular neurosis" as increased sensibility and a disordered action of the heart and vessels not dependent upon structural change. He also defined—and the term certainly needed definition—a "neurotic person" thus: "One may say that such a person is one whose whole nervous system, and especially that portion of it known as the organic nervous system, is hypersensitive and abnormally within his cognisance."

The excellent "System of Medicine" edited by Dr. CLIFFORD ALLBUTT has reached the fifth volume. This last addition contains articles on Diseases of the Respiratory and Circulatory Systems. A review has already appeared in our columns and it is unnecessary to again draw attention to the separate contributions. The whole publication will form a landmark in medical history and constitute the standard of reference for many years to come.

Dr. OSLER in the third edition of his "Principles and Practice of Medicine" has had the courage to introduce into the classification of diseases innovations which have long been foreseen but never adopted—namely, the inclusion of "Pneumonia" and "Rheumatic Fever" amongst "Specific Infectious Diseases." His decision in the former case will doubtless be accepted without cavil, whilst many authorities will prefer to wait before unhesitatingly removing the latter from the list of "Constitutional Diseases." Dr. ORD, as the Bradshaw Lecturer, chose for his subject Myxœdema and its Allied Disorders in their clinical aspect, considering their recognition, their differential diagnosis and their treatment. He expressed the opinion that the administration of the thyroid gland itself, when it could be carefully and regularly maintained, was the most appropriate form of treatment.

Great interest was naturally taken in the delivery of the HUXLEY Lecture on Recent Advances in Science and their Bearing on Medicine and Surgery, by Professor VIRCHOW. He propounded his original thesis that pathology is in reality a branch of biology. An especially interesting part of his address was the exposition of parasitism and the great extension which has been given to this study in the discovery of the minute parasitic agents which cause the infective diseases. He reminded his hearers that the reaction of the tissues and organs to the bacterial poisons forms an essential part of these diseases; he bade them remember that there may be some infections in whic

h

bacteria have no share; to the incalculable gains to humanity arising from the recognition of these agencies he bore ample witness, and he instanced the introduction of serum therapeutics as evidence of this assertion.

At the annual meeting of the British Medical Association held in Edinburgh three important discussions were held. Dr. ALEXANDER JAMES introduced the subject of the Clinical Varieties of Hepatic Cirrhosis; Dr. T. F. S. CAVERHILL that of the Open-air or Hygienic Treatment of Phthisis; and Sir WILLIAM BROADBENT that of the Significance and Consequences of Different States of Vascular Pressure, with their General Management. He devoted himself to a consideration of the resistance at the periphery; variations in intravascular pressure as occurring in the individual, or as presented by different persons, or in different states of health; the causation, significance, and treatment of low intravascular pressure; and, finally, the high intravascular tension and its treatment. He referred especially to the tension in uræmic convulsions and chronic bronchial catarrh, maintaining that in the latter while attacks may be warded off by wintering in warmer climates much more effectual relief may be afforded by eliminants.

Surgery.

In reviewing the work which has been done in surgery during the present year we are struck, not by any specially notable new departure either in the science or the art, but by the general progress which has been made in all departments. Operations which are now of almost daily occurrence once excited the attention and admiration of the surgical world, and this fact shows how much has been done to simplify and perfect our operative procedures so that even difficult operations can be undertaken with every reasonable hope of success. Perhaps it is in the surgery of the abdomen that the greatest progress has been made. On various occasions portions of the stomach have been removed for malignant disease, but it was reserved for Dr. CARL SCHLATTER of Zurich to remove the whole of the human stomach, and we were able to publish early in the year an account, specially translated for THE LANCET, of this heroic operation. The patient was a woman, fifty-six years of age, who for several months had suffered from persistent vomiting and an obvious swelling was felt above the umbilicus. When the abdomen was opened it was seen that the whole stomach from the cardia to the pylorus was converted into a hard mass of carcinoma. Gastro-enterostomy was impossible and Dr. SCHLATTER determined to attempt complete removal. The cardiac end of the stomach was separated from the œsophagus which had been clamped and the pylorus was also cut through. It was not found possible to bring the duodenum up to the œsophagus, so its open end was turned inwards and closed, and the œsophagus was united by lateral anastomosis to the jejunum about a foot from its commencement. Although some vomiting occurred for a few days, the patient's progress towards recovery was rapid and the latest reports of the case state that she is still in good health. Obviously a case like this is suited for solving many important physiological problems in digestion and numerous careful observations have been made. Since the publication of

Digitized by Google

Dr. SCHLATTER'S case, Dr. C. B. BRIGHAM of San Francisco has recorded a successful case of extirpation of the stomach. The patient was a woman, aged sixty-six years, who had suffered from gastric distress for a year, but by liquid food she was able to keep up her usual weight. In this case after removal of the stomach it was found to be possible to unite the duodenum directly to the œsophagus by means of a Murphy's button. Recovery followed and the patient was well seven weeks after the operation. The number of cases which will prove suitable for extirpation of the stomach will always be small, for it is inadmissible if the organ has become fixed, but in certain cases it offers a radical treatment where only palliative measures have hitherto been available. The survival and good health of Dr. SCHLATTER'S patient for nine months after the operation prove that the functions of the stomach can be dispensed with without the general well-being of the patient materially suffering.

Of late years a condition has been from time to time recorded to which the title of "idiopathic dilatation of the colon" has been applied. The etiology is obscure, but in many cases no obstruction exists, though it is possible that in some of the young children in whom it has been observed it was the result of congenital stenosis. The majority of the cases end fatally, but the formation of an artificial anus has in some cases resulted in recovery. Mr. FREDERICK TREVES has published a case in which the tolerance shown by the human body to the removal of large portions of the alimentary canal was strikingly manifested. A little girl, six years of age, had been the subject of idiopathic dilatation of the colon from birth and the interference with the onward passage of fæces was so great that Mr. TREVES made an artificial anus and nine months later he removed the whole of the descending colon, sigmoid flexure, and rectum, and brought the end of the transverse colon down to the anus where it was secured. The child made a speedy and excellent recovery. Another interesting case in which much large intestine was removed was that of a woman, thirty-three years of age, from whom Mr. R. LAWFORD KNAGGS successfully removed the cæcum and the ascending and transverse colon for malignant disease of the colon extending from the ileo-cæcal valve to the splenic flexure. Gastrorrhaphy or gastroplication is a recently introduced operation which has been devised for the treatment of non-obstructive dilatation of the stomach—it consists in infolding a portion of the stomach wall and fixing it with sutures. We published a successful case operated on by Mr. B. G. A. MOYNIHAN of Leeds in which a novel modification of the operation was employed. Mr. MAYO ROBSON has recorded 3 cases in which irregular muscular spasms were associated with dilatation of the stomach due to fibrous stricture of the pylorus. After pyloroplasty all the cases were relieved of the spasms which were probably the result of the absorption of toxins from the dilated stomach.

It is difficult to imagine a more serious surgical condition than acute general peritonitis, and the frequency of its occurrence amply justifies the recording of the comparatively few cases in which recovery has followed, and with our increasing knowledge of the powers of the peritoneum a favourable result is becoming increasingly frequent. The procedure to be adopted to cleanse the infected peritoneum must vary with the extent of the serous membrane which is implicated. If only a small portion is affected careful wiping with a sponge is sufficient, but with larger areas this becomes very difficult and in recorded cases recovery has followed the most diverse treatment; in some flushing with hot water has proved successful, in others the surgeon has carefully wiped all over the inflamed peritoneum, while in others merely a drainage-tube has been inserted, and yet the patient has not died. We can only imagine that the form of septic organism present has not been the same in all these cases, for it not rarely happens that the most energetic cleansing of the peritoneum is completely unsuccessful.

Rupture of the gall-bladder unassociated with injury to the liver is rare and therefore especial interest was felt in a case recorded by Dr. J. M. H. MARTIN of Blackburn in which rupture of the gall-bladder occurred in a boy, aged nine years, who was run over by a heavy cart; distension of the abdomen followed and though no jaundice was present the stools were clay-coloured. On opening the abdomen it was found that a large quantity of bile-stained fluid was free in the peritoneal cavity; 5 pints of this fluid were evacuated and a drainage-tube was inserted. Complete recovery followed. The difficult operation of suture of the bile-ducts after rupture or after removal of a calculus has been facilitated by an ingenious device of Professor W. S. HALSTED of Baltimore. This consists in a little hammer-shaped instrument by which the duct can be drawn up towards the operator, so that stitches can be fairly readily applied; it is likely to prove of great service.

Repeated aspiration in suppurative pericarditis has occasionally proved successful but generally it has failed. Dr. J. B. ROBERTS advocates incision after an exploratory aspiration has been performed to determine the presence of pus; in the method which he advises the fourth and fifth costal cartilages at the sternal junction are exposed and are divided, care being taken to avoid injuring the pleura, and on cutting through the soft tissues the surface of the pericardium is laid bare, and it can then be incised and the cavity drained or if necessary irrigated.

The surgery of the lung is practically the most recent of all the departments of surgery, and although it can hardly be said that at present very much has been done yet there is at least much promise for the future. Drainage of large tuberculous cavities in some cases saves a patient much distress even if it does not interfere with the onward progress of the disease. Mr. NORMAN PORRITT of Huddersfield considers that tuberculous disease of the apex of the lung has a natural tendency to heal by the drawing in of the chest wall over the diseased area, but that the rigidity of the ribs prevents this; he therefore suggests that portions of the second and third ribs should be excised both in front and behind in order to allow of this contraction, and he has performed the operation in three cases, in one of which much improvement followed, though in the two others death occurred a few days after the operation.

The treatment of peripheral aneurysms by ligature above and below and extirpation of the sac has been followed now in a large number of cases. We have published notes of one case in which Professor DÖLLINGER performed this

Digitized by Google

operation for an aneurysm of the iliac artery at its junction with the femoral, and the patient recovered without any adverse symptoms.

Arterio-venous aneurysm of the orbit has always been but little amenable to operation. Dr. J. H. WOODWARD of New York treated a case of this description by ligature of the left common carotid. Some temporary improvement followed, but complete recovery resulted after subsequent ligature of the arteries of the collateral circulation at the root of the nose.

The dangers of the treatment of carotid aneurysm by manipulation are so great that it is now never employed, but occasionally the examination of the aneurysm by the surgeon results in such displacement of the clot that solidification results; this was well illustrated in the case of a man who had been in the Royal Portsmouth Hospital but who left declining any operation; a few days after leaving the hospital pressure on the aneurysm by Mr. BOND of Havant was followed by cessation of the pulsation.

Mr. W. H. BENNETT contributed a useful paper on the Value of Massage in the Treatment of Recent Fractures. Although the method has been ably advocated by many surgeons, yet it is too little employed. By carelessness of course harm may result, but the benefits are so great that, as far as we are aware, no surgeon who has adopted the method has ever discarded it in favour of the usual treatment by complete fixation. In injuries and dislocations of joints also early massage goes far towards obviating the occurrence of the most troublesome sequelæ; and attention has recently been drawn to this matter by Dr. LUCIEN TIBERGHIEN of Brussels.

It is now generally recognised that basal meningitis, including the tuberculous variety, leads to a fatal result owing to the distension of the ventricles of the brain which is caused by the blocking of the foramen of Majendie. In such cases the only chance of relief is by draining the ventricles and this has usually been attempted by puncture through the vertex of the brain. About five years ago PARKIN suggested "basal drainage"—that is, the making of an opening into the subcerebellar space. This operation has been performed on several occasions and sometimes with success. We published a case under the care of Dr. OVEREND and Mr. CROSS in which this form of drainage was employed in a case of basal meningitis apparently traumatic in origin. Unfortunately, very little improvement followed, the child dying three weeks later; but although no benefit resulted the operation apparently did no harm.

Much attention was naturally attracted to the subject of fracture of the patella by the accident which befell H.R.H. the PRINCE of WALES. The result which has been obtained in that case has fully justified the decision of the surgeons who were consulted not to recommend the performance of any operation. In the majority of cases primary suture, if performed with complete asepsis, gives very satisfactory results.

The employment of COLEY'S fluid for malignant growths cannot even yet be said to stand on a certain basis, for even those who advocate its use claim that it only affects spindle-celled sarcomata. The great difficulty in appraising correctly the value of this remedy is due to the fact that the diagnosis of sarcomata is frequently very difficult, for it is often practically impossible to distinguish a sarcoma from an inflammatory growth. However the cases which have been recorded fully justify the administration of this substance in all cases of tumours which are thought to be sarcomata and which are not suitable for removal.

Obstetrics and Gynæcology.

One of the most interesting events of the year has been the appearance of the English translation of Professor SCHENK'S work upon the production of sex. His theory, shortly, is as follows. If the tissue metabolism of the mother is carried on in the highest possible perfection she is likely to bear a male child. If, on the contrary, her metabolism is imperfect, as shown by the presence of sugar in the urine, she is more likely to bear a female child. Professor SCHENK in cases where male children are desired endeavours to rectify any faulty metabolism by appropriate diet and judges of his success by the examination of the urine for sugar. It is evident that this theory does not provide for the production of female children and is not applicable to cases where the mother's metabolism is already perfect. It remains to be seen whether Professor SCHENK'S theory of the determination of sex will hold its own or whether it will not quickly pass into oblivion, like the many other theories which have preceded it.

At various times the treatment of uterine fibroids by ligaturing the uterine arteries and so cutting off their main blood-supply has been advocated. The recent anatomical studies of M. FREDET have shown that the uterine arteries practically supply the whole of the uterus and that the ovarian artery sends a very small and comparatively insignificant branch to anastomose with the uterine. This anatomical fact explains the remarkably good results which often temporarily follow the ligature of the uterine arteries, since until the anastomotic branches become enlarged ligature of these arteries cuts off practically the whole blood-supply to the uterus. Dr. HOFMEIER'S work upon the cilia of the uterine epithelium has been lately confirmed by Dr. MANDL who finds that the current produced by their action is from the fundus of the uterus to the cervix and therefore against the course of the spermatozoa. An important contribution to the anatomy of the third stage of labour has been made by Professor STEPHENSON who has published a plate of the uterus with the placenta still *in situ*.

There has been a considerable amount of activity during the past year in both obstetrical and gynæcological practice and although no very new departure has been initiated yet many old theories have been confirmed and others shown to be no longer tenable. An interesting discussion took place at the British Medical Association meeting upon the use of forceps. The debate was opened by Dr. MILNE MURRAY and continued by many obstetric authorities. On the whole, opinion seemed to be upon the side of axis-traction forceps as the best type of instrument, and there was a considerable amount of dissent expressed from the views as to the abuse of forceps at the present day put forward by Professor SINCLAIR at the meeting in 1897. One of the most interesting obstetrical cases recorded in THE LANCET during the past year was one of

Digitized by Google

incomplete retroflexion of the gravid uterus related by Dr. HERMAN in which the patient, a primipara, was prematurely confined at the eighth month without interference. The child presented by the breech and was born dead, but the mother did well. As the writer points out interference in such cases is uncalled for and as a rule useless. The treatment of irreducible cases of incarcerated retroverted gravid uteri by abdominal section has been further tested by Professor JACOBS of Brussels who has treated 11 cases in this way with very good results, abortion occurring after the operation in only one case. Such a mode of treatment would certainly appear to be justifiable where the only other alternative is the production of abortion. A most important contribution to the study of Cæsarean section has been the publication by Professor LEOPOLD of the results of 100 cases of Cæsarean section and Porro's operation. He considers the conditions under which the operation may be done must include the means of attaining most rigorous asepsis. He therefore thinks it should not be performed except in a properly equipped institution. The conditions necessary for the conservative operation he lays down as follows: (1) that the woman in labour has energetic contractions of the uterus; (2) that the general health has not been enfeebled; and (3) that it is certain that the patient has not become infected at the time of the operation. He also insists upon the fact that the operation must not be performed upon a patient the subject of gonorrhœal infection, whether acute or chronic. There were 7 deaths amongst the 71 cases of Cæsarean section, or 9·8 per cent., and 3 amongst the 29 cases of Porro's operation, or 10·3 per cent. All the children of the cases of Cæsarean section lived, while 2 of the children died during the performance of Porro's operation. In conclusion the author compares his results with those of symphysiotomy as published by Professor MORISANI, Professor PINARD, and others, and finds that the rate of mortality is slightly in favour of the Cæsarean section. The method of making a transverse incision in the uterus in performing Cæsarean section recommended by Professor FRITSCH last year has been adopted with good results by several other surgeons. It promotes contractions of the uterus, renders the control of hæmorrhage more certain, enables the child to be extracted with ease, reduces the risk of subsequent hernia as it allows the incision in the abdominal wall to be made higher up, and assists in preventing the escape of blood or amniotic fluid into the peritoneal cavity.

At the end of last year a paper was read before the Obstetrical Society of London by Dr. MACKERRON upon the Treatment of Ovarian Tumours Complicating Labour. The author had collected 183 cases and concluded that reposition should be tried in all cases, while if this failed resource must be had to puncture of the tumour, Cæsarean section, or abdominal or vaginal ovariotomy. Professor SPENCER related a case of a dermoid tumour removed during labour by abdominal ovariotomy, the child being delivered by forceps *per vias naturales*, both mother and child doing well. In the discussion upon Dr. MACKERRON'S paper the general opinion appeared to be that this was probably the best method of treating such cases when reposition was impossible. M. LINDENTHAL has succeeded in isolating an anaerobic bacillus which he regards as the essential factor in producing the conditions of physometra or gas in the uterus. He has also succeeded in producing an analogous condition by introducing a pure culture of the organism into the amniotic cavity of a pregnant bitch.

A very valuable addition to our knowledge of ectopic gestation has been made during the year by the delivery of the Ingleby Lectures for 1898 upon this subject by Mr. JOHN W. TAYLOR. It is astonishing to think how our knowledge of this condition has grown during the last few years and these lectures derive an additional importance from the fact that we owe much of our knowledge to their author. Mr. TAYLOR draws attention to Professor LEOPOLD'S important and recent case of utero-abdominal gestation. The patient ruptured her uterus by falling down stairs two or three weeks before quickening. At the operation at term the dead fœtus was found lying in a thin sac in the abdominal cavity, the cord passing into the uterus through a perpendicular opening 2 cm. long behind the right broad ligament. An uninterrupted recovery followed.

Numerous cases of puerperal septicæmia have been recorded from time to time during the year in our columns in which the treatment by anti-streptococcic serum has been carried out. Unfortunately from the absence of any bacteriological examination many of these cases are valueless as proofs of the efficacy of the treatment. Now that we know that puerperal septicæmia may be due to a variety of organisms it is most essential that whenever possible a bacteriological examination of the contents of the uterus should be made so that a definite conclusion may be come to as to the value of the serum. The matter was discussed at a meeting of the Obstetrical Society when very different opinions were expressed as to the value of the treatment. At the present time it may be said that while the injection of anti-streptococcic serum in cases of puerperal septicæmia does no harm it has yet to be proved that it does much good. A very important *résumé* by Dr. COBBETT of the whole subject appeared in our columns in April.

At the British Medical Association meeting in the Gynæcological Section a discussion was opened by Dr. CULLINGWORTH upon the Treatment of Pelvic Inflammation. The subject was considered under the two heads of the indications for operative interference in pelvic inflammation and the choice of time for operation. The conclusions arrived at with regard to operative interference were that it was as a rule necessary in all cases where there was pus present; in cases where after the acute attack had subsided a swelling still remained which showed no signs of diminishing or even grew larger, as, for example, in cases of hydrosalpinx or diseased ovaries; and in certain cases of non-suppurative salpingitis where the patient belonged to the labouring classes and where it was important that she should be restored to health as soon as possible.

With regard to the choice of time Dr. CULLINGWORTH was of opinion that any operative interference should be avoided as far as possible during an acute attack. The discussion which followed was one of great interest, as the speakers included Professor DOYEN of Paris, Professor JACOBS of Brussels, Professor LANDAU of Berlin, Professor SAENGER of Leipzig, Professor FEHLING of Halle, and Professor MARTIN of Berlin.

An important communication was made in May by Mr. ALBAN DORAN to the Obstetrical Society amplifying his previous paper upon the subject and including all the cases, 23 in number, of Primary Carcinoma of the Fallopian Tube recorded up to April, 1898.

Among the papers read before the British Gynæcological Society was one by Dr. BANTOCK upon Dysmenorrhœa and one by Dr. PURCELL upon the Risks to the Ureters when performing Hysterectomy, illustrated by a case in which both ureters were occluded and freed fifty-eight hours afterwards.

The operation of ovariotomy has been performed both upon the very aged and the very young, but the youngest successful case would appear to be that of a child, aged four months, reported by Mr. D'ARCY POWER to the Pathological Society in March last in which he removed a multilocular ovarian cyst. The question of the best method of operating in cases of carcinoma of the uterus still occupies very largely the attention of gynæcologists. The method of removing the uterus by abdominal hysterectomy with a free excision of the broad ligaments and removal of all the glands lying in the cellular tissue appears to be gaining ground. There can be no doubt that an operation of this kind is more in keeping with the trend of modern surgery than the relatively more incomplete operation of vaginal hysterectomy. Whether the ultimate results will render the additional risk of such a procedure justifiable remains to be seen. There appears to be no reason why the modern methods of removing the disease as widely as possible should not be applied to the uterus as well as to other viscera in the body. A number of cases have been operated upon in this way during the past year and the immediate results of the operations show that the mortality has been definitely diminished, and no doubt further experience will tend to produce still better results. The question as to whether a sound can be passed into the Fallopian tube or not would appear to be set at rest by a case recorded by Dr. HIND in which a sound was actually found lying in the tube on abdominal section. The sound in this instance passed in a distance of 8 in. and protruded at the abdominal ostium of the tube. Attention has been drawn in our columns to the application of steam to the interior of the uterus and it was shown that this method was not without its dangers, several cases having been recorded where the uterine cavity had been completely obliterated as a result of its employment. A good deal of attention has been paid to this mode of treatment lately and if used with due precaution it may prove of value in suitable cases where curettage even when repeated has failed to arrest hæmorrhage.

The past year has been unusually prolific in the production of new works upon midwifery and gynæcology, some of them of great merit.

Therapeutic Progress.

Perhaps one of the events of the greatest interest in the current year has been the production of the long promised British Pharmacopœia. It is not customary to look to the Pharmacopœia for new drugs, but to a great extent the Pharmacopœia indicates the trend of modern thought in the administration of remedies and it undoubtedly greatly influences the teaching of medical students, while it also affects the practice of medical men. For a short time after a new issue has been published some degree of chaos usually results. New remedies are introduced, new preparations are substituted and doses are altered, and the more conservative members of the profession are perhaps prone to rebel against the interference with their daily routine. In the Pharmacopœia of 1898 the comparative absence of complaints in the medical journals appears to indicate that changes affecting practice have been made with the greatest caution and that these changes are generally welcomed. The elimination of antiquated material has been performed with considerable tact and there have been but few protests against the extremely lengthy lists of drugs and preparations omitted from the last British Pharmacopœia. On the other hand, the additions appear to have given general satisfaction, and amongst the criticisms to which the volume has been subjected there have been but few suggestions for other additions. Amongst pharmacists it is true that some degree of criticism has arisen, but it would be impossible to expect any volume which is full of directions to pass unchallenged and although now more than six months have elapsed since its appearance the new Pharmacopœia has not yet been charged with any serious error or misstatement.

The publication of the Pharmacopœia has necessarily led to the publication of new editions of text-books on materia medica and the year is also noteworthy for new editions of several text-books on therapeutics.

At the meeting of the British Medical Association in Edinburgh the Therapeutic Section devoted three days to Discussions—(1) upon the Treatment of Diseases of the Stomach; (2) upon the Treatment of Chronic Renal Disease; and (3) upon the Therapeutic Value of Recent Synthetic Analgesics. In the first discussion Professor EWALD of Berlin made a valuable contribution, summarising the influence of treatment upon the gastric chemical processes, while Professor TURCK of Chicago read an interesting paper on the Treatment of Dilatation of the Stomach by a System of Gastric Gymnastics. In the discussion on Chronic Renal Disease, introduced by Dr. TIRARD the subjects chiefly considered were the value of pilocarpin in the treatment of uræmia and the administration of morphine in the presence of uræmic convulsions. On neither of these points, however, were the speakers unanimous. Professor STOCKMAN gave an interesting account of the risks of the various recent synthetic analgesics and he was followed by Dr. C. D. F. PHILLIPS, who spoke in favour of antipyrin, antefebrin, phenacetin, and exalgin.

Amongst the other papers read at this meeting may be mentioned that by Professor CASH dealing with the pharmacology of the alkaloids of aconite; one by Dr. GILLESPIE on the Value of Bromide and Iodide of Strontium for Exophthalmic Goitre in Children; and one by Dr. MCWALTER of Dublin propounding numerous curious criticisms upon the Pharmacopœia and upon the mode of its production.

Comparatively little has been added to our knowledge of the local anæsthetics. Less is now heard of the value of eucaine, while the actions of holocaine have been further investigated. Methylene blue continues to attract attention, but it is somewhat difficult to group its actions since it has been employed for such a variety of conditions. It has been

Digitized by Google

used in malaria and has been credited with possessing prophylactic as well as curative properties. It has also been employed for the relief of pains varying from the lightning pains of locomotor ataxy to slighter forms of facial and sciatic pains. It has also continued to be administered in gonorrhœal urethritis and benefit during its administration is claimed in some few cases of diabetes mellitus.

The list of antiseptics has not been greatly extended during the year. Protargol has been employed in the treatment of ophthalmia and in acute conjunctivitis, while further advocates have been found for chinosol and iodoformogen, the latter being substituted for iodoform.

For the treatment of cardio-vascular troubles the more general employment of morphine has been advocated and its effects have been attributed to its influence upon the nervous apparatus of the cardio-vascular system, both central and local. Periplœin, a glucoside from periplœa græca, has been found to increase the blood-pressure, to reduce the frequency of the pulse, and to act as a diuretic like digitalis, while it can be administered more easily by hypodermic injection.

In the early part of the year an interesting paper appeared in our columns summarising the actions of creosote and of guaiacol and giving a description of creosotal, for which certain advantages were claimed, the chief being that it provoked less gastro-intestinal trouble. Other remedies which have been employed in the treatment of tuberculosis are guaiacolate of piperidin, cinnamic acid, and geosote. Of these cinnamic acid has been applied hypodermically, but it possesses the great disadvantage of producing severe burning pain. Geosote is a valerianate of guaiacol which may be employed internally or administered by subcutaneous injection. For all three of these remedies good results have been claimed. There is very little that need be said of the drugs influencing the digestive system. Although many papers have appeared on this subject they have in the main followed well-beaten lines. It is true that a new vermifuge named "tenaline" has been suggested, but hitherto it has only been administered to animals and it does not appear to be wholly devoid of danger.

Sparteine sulphate, the active principle of broom, has been recommended for the treatment of dropsy, and it has been claimed for this remedy that it is an efficient diaphoretic which is less nauseous than other preparations of broom. Diuretin has also been discussed and it is said to have given good results in cases of chronic tubal nephritis after digitalis had ceased to act. Dr. DRESCHFELD states that occasionally with cirrhosis of the liver he has found benefit when the symptoms have arisen suddenly, while little relief was given when the onset had been more gradual.

The influence of drugs upon gout forms the subject of some papers which appeared in our columns. The general result of some experimental researches appears to be that alkalies, lithium salts, piperazine, and lysidine exert no special solvent effect upon sodium biurate, while sodium salicylate not only has no special solvent action, but leads to an increased formation of uric acid in the kidneys.

Veratrum viride has been used in a case of puerperal eclampsia and, inasmuch as it relieves arterial tension and causes diminution of the pulse-rate, it has been credited with good results.

The year has shown continuous research for remedies which will influence the growth of cancer, or which will control tuberculous processes either in the lungs or in the joints. Chelidonium has been recommended for cancer and it appears to produce much local irritation when injected in the neighbourhood of new growths. It was at one time hoped that the x rays would be of service in the control of tuberculosis, but recent observers maintain that they possess no therapeutic efficacy. In tuberculous caries and in gland affections chinosol has given some satisfaction. Whooping-cough, which forms such a cheerful field for investigation, has been treated with pertussin, a proprietary preparation of thymol, which has been strongly recommended; while one observer has recently advised syringing out the ears night and morning with lukewarm boric solution or water, and the application to the meatus and tympanum of a paint containing hydrochlorate of cocaine, glycerine, and perchloride of mercury.

The foregoing account sufficiently indicates that both medical men and chemists continue to prosecute researches unremittingly and in many directions. The interest in producing new antiseptics, new antipyretics, and new hypnotics has largely given place to a struggle with tuberculosis. There is a growing belief in the efficacy of the "open-air" treatment, but work continues meanwhile with respiratory antiseptics. Some therapeutic habits have been challenged as though they were articles of belief but improvement in our resources must result from scepticism and inquiry and our treatment must benefit as it is thus rendered less empirical and more scientific.

Ophthalmology.

The Bowman Lecture was delivered by Mr. PRIESTLEY SMITH who, whilst fully recognising the value of optical treatment in strabismus and the frequent necessity for operative procedures either by tenotomy of the stronger or by the advancement of the weaker muscle, yet availed himself of the opportunity of warmly advocating the orthoptic or, as he prefers to name it, the "educative" mode of treatment, in which the patient is taught the forgotten art of binocular vision by means of the monocular shade, the reading bar, the stereoscope, and other exercises—a method practised with good results by M. JAVAL in Paris but somewhat neglected elsewhere.

Several new remedies have been recommended such as euphthalmin, itrol, protargol, airol, holocaine, and various others none of which seem to be superior in reducing inflammation to such old-fashioned remedies as alum and nitrate of silver or more effective in their action on the pupil than atropine or eserine.

It is not right to make *a priori* statements or to limit the powers of nature, but we should hardly expect that detachment of the retina and sundry other affections of the eye could be advantageously treated by a glycerine extract of ciliary body and vitreous humour taken by the mouth or injected subcutaneously as recommended under the name of "oculine" by Dr. LAGRANGE of Bordeaux. M. FROMAGET, however, states that he has found the aqueous extract of the adrenals to be of service in the treatment of various forms

Digitized by Google

of conjunctivitis and blepharitis as an adjunct to antiseptic measures and that it has a powerful hæmostatic effect in hæmorrhage.

The Roentgen rays have been used with success on different occasions by HOTZ, STARR, DE SCHWEINITZ, and others, and instruments have been devised by Mr. MACKENZIE DAVIDSON in this country and by Dr. SWEET in the United States to overcome the difficulty of locating with exactness the position of the foreign body in view of the great thickness of the region through which the rays have to pass. A remarkable circumstance noted by M. FOVEAU DE COURCELLES was thought by him to be of sufficient importance to be brought under the notice of the French Académie des Sciences—viz., that amongst 204 blind children 5 boys and 4 girls were able to recognise the Roentgen rays. Some saw the x, cathodic, and fluorescent rays, others only the cathodic and x rays, and one described them as being of reddish colour.

The importance of preventing the introduction of trachoma or "granular lids" into a community or of eradicating it by prompt and effective measures is shown by the observation of FEUER in Hungary. In that country there are between 7,000,000 and 8,000,000 inhabitants and the proportion of trachomatous patients is no less than 4 per 1000. He believes it to be independent of nationality, soil, race, altitude, and even of cleanliness, since the Tsiganes who are certainly the dirtiest are the least affected. It spreads by contagion and its ravages are so serious that not only is subjection to treatment made compulsory, but neglect on the part of the patient is liable to fine and even to imprisonment.

Dr. PRIOUZEAU has been led from his observations to establish a connexion between chalazion and ametropia, for he finds that 70 per cent. of cases of chalazion are hypermetropic, 12 myopic, and 13 astigmic, whilst the most careful research has failed in his hands to demonstrate the presence of a microbe to account for the disease.

In view of the fact that certain forms of lenticular cataract, and especially those presenting equatorial striæ, develop in many instances very slowly or remain stationary for months or years there is good sense in the opinion expressed by Dr. HOTZ of Chicago, that the word "cataract" should not be mentioned to the patient except where the disease is moderately advanced or a positive statement demanded, for the quacks who state that they can cure cataract by absorption, electricity, or prayer are apt to claim the retention of vision as the result of their operations, and to throw discredit on legitimate means of relief. It may be remarked that Professor SCHMIDT-RIMPLER has brought together several cases of the clearing up of cataracts recorded by reliable authorities and gives the details of two which were seen by himself, and Professor EWALD of Strasburg describes a condition of haziness of the lens in a rabbit which he was able to remove or disperse without operation.

The subject of glioma of the retina was discussed in the Ophthalmological Section of the American Medical Association which met last summer at Denver. Dr. J. Q. THOMPSON, who introduced the subject, had seen 13 cases of glioma of the retina in the course of twenty-seven years out of 24,500 cases, whilst it was stated that a Parisian ophthalmologist had only seen 4 cases of glioma out of 50,000 cases. Like cancer in other parts of the body, it is irregularly distributed and it appears to be more frequent in the negro than in the white man. In the discussion which followed it was agreed on all hands that the only treatment which promised success was early and complete excision of the eye with removal of the contents of the orbit if the disease was not in an early stage and strictly confined to the globe.

A novel and somewhat startling application of physiological knowledge to the treatment of disease has been made by MM. ABADIE and JOANNESCO who recommend ablation of the superior cervical ganglion or section of the sympathetic cord in the neck on both sides for the treatment of glaucoma. That such an operation amongst other effects lowers the tension of the globe is undoubted, whilst that the tension can be raised by galvanisation of the upper extremity of the divided nerve was shown by the late Dr. BROWN-SÉQUARD, but its mode of action in relieving glaucoma, as Dr. CAMPOS remarks in an article contributed to the *Recueil d'Ophtalmologie*, is not clear and is, indeed, in opposition to the generally accepted explanation of the nervous origin of glaucoma. It seems to be a formidable proceeding considering our ignorance of the secondary effects which may occur in man, but the preservation of sight is paramount to most considerations. Dr. HUGUENIN has performed a useful labour in following up the ultimate effects of the ordinary treatment of glaucoma by iridectomy in 76 patients operated on in private practice by Dr. HAAB of Zurich, and his observations are encouraging since they show that the tension of the eyes is permanently reduced by the operation and that the vision improved not only in acute but also in subacute and chronic cases of the disease.

It would appear that small degrees of astigmatism, if with reversed axes in the two eyes are especially troublesome to the patient, and Dr. GEORGE M. GOULD records a case of severe and repeated sub-conjunctival hæmorrhages where this condition having been diagnosed under atropine the employment of suitable corrected glasses prevented any recurrence of the affection. Dr. OSTWALT strongly recommends, both on practical and on theoretical grounds, the use of periscopic glasses—that is to say, of menisci with the convex surface outwards and the concave next the eye in all myopic cases instead of the biconcave glasses in ordinary use. Dr. BERNHEIMER has availed himself of opportunities to study the origins of the third nerves after removal of the globe, with the result that he finds that the branch to the inferior rectus has a crossed origin, that the branch to the inferior oblique has the major part crossed, while that to the internal rectus is both crossed and direct and those to the superior rectus and levator palpebræ are direct.

Two very finely illustrated works have recently been published, both of which are highly creditable to their authors and useful alike to teachers, practitioners, and students. The first of these is the Ophthalmoscopic Atlas by Mr. ADAMS FROST, the ophthalmic surgeon to St. George's Hospital, which contains many well-executed chromo-lithographed plates of the fundus oculi and numerous woodcuts, whilst the accompanying letter-press gives the results of his large experience. The second is a

Digitized by Google

Atlas of External Diseases of the Eye by Dr. A. MAITLAND RAMSAY of Glasgow who has made an advantageous innovation by appending to the 30 full-page coloured plates, each presenting several diseases depicted with great accuracy and delicacy, a series of full-page photogravures which supply life-like representations of diseases not otherwise so well exhibited. A Student's Manual on Diseases of the Eye has also been published by Mr. JESSOP, one of the ophthalmic surgeons to St. Bartholomew's Hospital.

In accordance with the general principle of evolution, and just as the modern surgeon is the outcome and higher phase of the barber-surgeon, so the Spectaclemakers' Company are desirous of blossoming into a scientific craft, or at least of introducing scientific knowledge amongst the highly intelligent artisans in their workshops, and have instituted a system of examinations which will probably have a beneficial effect for the public by causing ophthalmic surgeons to bestow their utmost care and pains on the cases of refraction which come under their charge, knowing that in the skilled optician they will have a keen critic well acquainted with the properties of lenses and prisms and accustomed to the most precise and delicate work. The optician's diploma question seems to have aroused more interest in America than in this country, perhaps owing to the more highly strung nervous systems of the Americans leading them to seek relief from glasses in conditions which would be borne without complaint in England. Hence a large number of ophthalmic surgeons have arisen and doubtless some clashing of interests occurs.

Here there is, we think, little chance of unpleasant friction between the surgeon and the optician. After obtaining his diploma—if the Spectaclemakers' Examination is conducted on the same lines as those mapped out by Dr. LINDSAY JOHNSON and his coadjutors in the first examination which has just been held—the optician will be a highly instructed and competent man. The ophthalmic surgeon must be content to know that some of the patients who would have applied to him have gone to the optician; but, on the other hand, the optician will with larger information recognise that there are numerous cases which require a different kind of knowledge from that which he possesses and he will, if he be wise, transfer them to the ophthalmic surgeon. There will be no loss on either side and the patient will benefit, which, after all, is the result to be achieved.

Forensic Medicine.

The year has been memorable in the annals of Forensic Medicine chiefly on account of the unprecedented number of prosecutions of persons charged with having attempted or procured criminal abortion. It is sad to contemplate that in several instances the accused has been a qualified or formerly qualified medical man. It was high time that the law should be set rigorously in motion since there was overwhelming evidence that the odious crime was practised with alarming frequency. JAMES CHARLES ADY was convicted at the Central Criminal Court and sentenced to seven years' penal servitude for having attempted to procure abortion and for conspiracy with a man named TOMASSO. WILLIAM MAUNSELL COLLINS, a medical man who had previously been convicted for forgery (and whose name had been removed from the Medical Register) and who, there is reason to believe, was an habitual abortionist, was found guilty of the manslaughter of Mrs. UZIELLI and sentenced by Mr. Justice GRANTHAM to seven years' penal servitude. More recently JOHN LLOYD WHITMARSH was tried for the murder of a single woman named ALICE BAYLY by using an instrument and by the topical use of a mercurial salt. Mr. Justice BIGHAM who presided at the trial ruled that if the jury found that the prisoner had acted feloniously they must return a verdict of "Wilful murder," which they accordingly did and WHITMARSH was sentenced to death. The punishment was subsequently commuted to twelve years' penal servitude. We cannot help remarking the disparity between the sentence in this case and that of COLLINS. In THE LANCET of Dec. 17th will be found an account of the recent trial at the Kent assizes of Dr. DAVID WALLACE, a medical man in practice at Beckenham, who was indicted for having ravished a young woman named WARRILOW whilst in a state of unconsciousness and for having criminally induced abortion. Dr. WALLACE was acquitted of the latter offence and no evidence was offered by the prosecution on the former charge. The case illustrates the desirability of a medical man insisting on the presence of a third person when a particular examination has to be made on a female patient. Mr. JAMES BROWN, a physician and surgeon of Wigan, was charged with having unlawfully used an instrument and procured the abortion of JANE SHARPLES, aged twenty years. The case is remarkable in that Mr. BROWN was found chargeable by the coroner's jury with having by illegally procuring the miscarriage of SHARPLES contributed to the death of the child prematurely born. The magistrates dismissed the charge of inducing abortion. The Public Prosecutor preferred an indictment at the assizes, but the grand jury very properly, in our opinion, threw out the bill.

A woman named NANCY BEDFORD of Wigan was awarded six months' hard labour for having supplied medicine containing colocynth, aloes, and savin, and pills containing hellebore, aloes, and savin, with the intent to procure abortion. At Milford a woman named ANN COURTNAGE, aged twenty-four years, lost her life from septicæmia and peritonitis consequent on miscarriage brought on by taking in excess pills containing aloes (3½ grs.). The pills were contained in a box having the Government stamp upon it and were represented as having been supplied by a person who had been connected with a women's hospital. We would draw attention to Dr. LUFF'S evidence that where such drugs as were contained in these pills did procure abortion (and they generally failed) they nearly always procured it at the cost of the life of the woman. This case showed the necessity for legislative enactment forbidding the sale of substances injurious to health and dangerous to human life.

The cases of WHITMARSH and WARK who were sentenced to death for procuring abortion direct attention to the desirability of an alteration in the law either by making the crime one of manslaughter only or by recognising "degrees of murder." Though legally guilty of the crime of murder according to the statute the offence is in some sense extenuated by the fact that it is not committed with

Digitized by Google

malice aforethought and that there is no intent to take away life.

Before dismissing from notice this hideous blot on social life we may refer to the case of GOFF *v.* GOFF and GORDON in which Dr. GOFF sought a divorce from his wife. The respondent pleaded amongst other things that her husband had been guilty of cruelty—in fact, she practically charged him with having procured criminal abortion upon her. The jury found for the petitioner on all issues. To this verdict we gave unqualified assent.

Several trials for infanticide of newly born children by their mothers have ended in acquittal although there was the clearest evidence that the offspring were legally born alive and that their deaths were due to violence or neglect. Judges have naturally—and, as we think, rightly—a tendency to direct juries very strongly that they must be certain before convicting that the unhappy women were in such a state of mind at the parturient period as to render them criminally responsible. Something more than the alternative of "concealment of birth" is required to meet the occasion. Here, again, we are of opinion that an alteration in the law is called for.

It is difficult to move the legislative machinery or long ere this a more scientific and comprehensive definition of criminal responsibility would have been forthcoming. The old criterion of "the knowledge of right from wrong and of the nature and quality of the act" is still the legal test of insanity as bearing on criminal charges. Certain of our judges are disposed to give a wider interpretation of the law than is logically justified, but there are others who adhere to the terms of the statute with unflinching integrity. At the Gloucester assizes where a lad named ALBERT GRIFFITHS was tried for the murder of a farmer by stabbing him to death, although no premeditation was proved and although there was a strong presumption that the prisoner's mind was disordered Mr. Justice DAY refused to admit the evidence of an expert medical witness as to his opinion of the condition of mind of the accused at the time of the murder.

We have on many occasions reverted to the question of "professional secrecy," still a vexed question. We had occasion to express the belief that a medical man engaged by an employer to attend his employés has no right to divulge facts relating to the illness of the patient which he has become possessed of in his professional capacity unless the patient gives permission or that it is desirable in the public interest. A medical man cannot contract with an employer for other than attendance on the employé.

Several actions, criminal and civil, have been brought against medical men. Mr. L. V. PARRY of Birmingham was charged with a criminal assault on a woman who had been treated for hysteria. To the credit of the prosecution be it said the case was withdrawn when it came on for hearing.

Dr. H. COLGATE and Mr. G. A. SKINNER were sued for damages for "neligence in treatment and false imprisonment." The judge agreed with the verdict of the jury that the evidence utterly failed to support the allegation.

A remarkable trial which lasted six days in the Probate Court was that of KINGSBURY *v.* HOWARD. Dr. KINGSBURY who had attended the testatrix was left as her residuary legatee. It was sought to establish that by hypnotic suggestion Dr. KINGSBURY had induced the deceased lady to make her will in his favour. The jury found this not proved and the provisions of the will were undisturbed.

The Court for the Consideration of Crown Cases Reserved have unanimously decided that THOMAS GEORGE SENIOR was properly convicted of the manslaughter of his child through not having called in medical aid. It will be remembered that the prisoner belonged to the sect called the "Peculiar People." At the November sessions of the Central Criminal Court he was convicted of manslaughter. Mr. Justice WILLS who tried the case eventually passed sentence of hard labour for four months. The judgment of the higher criminal court is in accordance with common-sense and common humanitarian principles.

CAMILLA NICHOLLS was sentenced to seven years' penal servitude for the manslaughter of her servant EMILY JANE POPEJOY. The prisoner had habitually starved the girl and had mercilessly assaulted her on several occasions. As we wrote at the time, she was guilty of "criminal omission of duty and commission of illegal acts."

The most notorious case of poisoning which has happened during the year was that for which WALTER HORSFORD was convicted, sentenced to death, and executed for having murdered his cousin, ANNIE HOLMES, by giving her a huge quantity of strychnine. The motive was the utterly inadequate one of getting rid of a source of annoyance. HORSFORD had had immoral relations with the woman who represented to him her belief that she was *enceinte*—although such was not the fact.

It seems that in certain parts of the country it is a common practice for women to take diachylon to procure abortion. Dr. G. F. CROOKE has given us an exceedingly interesting account of a fatal case of acute lead poisoning. The woman had succeeded in inducing abortion by eating diachylon.

A man died at Aston from acute congestion of the lungs caused by inhaling nitric fumes. His occupation was that of dipping copper cups in dilute nitric acid. A child, aged eight years, succumbed to the effects of poisoning by privet berries. The wife of a medical man died from swallowing a solution of cocaine. The act seems to have been a suicidal one. A rare case of poisoning by paraffin oil happened to a child, aged fourteen months. One and a quarter ounces of the oil were swallowed and death ensued in one hour and fifty minutes.

We would draw attention to the presentment of the Public Control Committee of the London County Council to the Home Office in the matter of the enrichment of coal-gas with water-gas for public purposes. They recommended amongst other things (1) that non-carburetted and non-odorised water-gas should not be used under any conditions; (2) that not more than 25 per cent of water-gas should be used in the enrichment of coal-gas; and (3) that where the enriched gas is employed it should be under official supervision and inspection. We cordially endorse these recommendations seeing the great danger of poisoning by carbonic oxide.

Dental Surgery and the Practice of Dentistry.

The past year will always be memorable in the annals of dental surgery from the fact that for the first time in the

Digitized by Google

history of the profession a dental surgeon obtained a seat on the General Medical Council. The British Dental Association for some years has been bringing the claims of dentists for representation on the Council before the proper authorities and so persistent have been the efforts and so reasonable the request that it is not unnatural that Mr. CHARLES TOMES should have been appointed to the vacancy caused by the death of Sir RICHARD QUAIN.

During the year several papers have been published which have advanced the knowledge of dental pathology. Dr. ZNAMENSKY of Moscow, in a communication to the January and February issues of the *Journal of the British Dental Association*, recounted some interesting experimental investigations he had made on the pathology of erosion. Mr. STORER BENNETT endeavoured to repeat these experiments but in the majority of instances he was unable to achieve the same results as Dr. ZNAMENSKY. Although the results obtained by these investigators are so different, the manner in which the subject was approached is undoubtedly excellent and it is quite possible that by further repetition, modification, and development of the experiments in various ways substantial results may be obtained. A paper from the pen of Mr. A. S. UNDERWOOD on Erosion has also appeared and he has described certain minute defects in the structure of the enamel of teeth attacked by erosion. The pathology of dental cysts has been considerably advanced by the researches of Mr. J. G. TURNER. From a thorough microscopical examination of many specimens he has been able to show pretty definitely the development of these cysts from aberrant masses of epithelium met with in the alveolo-dental ligament. He has also demonstrated that the exciting cause which starts activity in these epithelial masses is septic matter from pulpless teeth. Mr. TURNER in the same paper described three specimens of gingival cysts and suggested that in all probability they originated from the masses of epithelium found in the substance of the gum and known as "glands of Serres." Mr. KENNETH GOADBY in a paper read before the Odontological Society has added to the knowledge of micro-organisms of the mouth, and Mr. DENCER WHITTLES claims to have found a micro-organism which he considers the cause of pyorrhœa alveolaris, but the details so far given by him are somewhat meagre.

A paper by Mr. HOPEWELL SMITH has thrown a good deal of fresh light on the Healing Processes of the Dental Pulp and an easy and exact way of estimating the amount of potassium sulpho-cyanide in the saliva has been introduced by Mr. H. ALBERT. Ankylosis of Teeth to the Jaws formed the subject of a paper by Mr. STORER BENNETT, and from the illustrations given there can be no doubt that under certain conditions ankylosis of teeth to the jaws may take place.

No special advance has been made in operative dental surgery. The use of crowns as a method of treating teeth much affected by caries has come into increased favour, while bridge work is being adopted with more caution and judgment. The conservative treatment of the pulp has attracted a fair share of attention due to the introduction of various preparations claiming to have as their active ingredient formalin. A plan by which the tedious processes of cleansing and filling pulp canals could be overcome would be a great step in advance not only to the patient but also to the operator, and although the methods of mummifying or preserving pulps have not proved constantly successful the prospect certainly seems encouraging, and with an increased knowledge of the pathology of the pulp and the actions of drugs on that tissue a satisfactory plan will no doubt be evolved in the near future.

The use of oxy-phosphate of zinc with amalgam has come into more general use and the experience of practice shows that it is possible to insert reliable fillings by this method. The prolongation of nitrous oxide anæsthesia has attracted much attention and the methods advocated by Dr. MCCARDIE, Mr. H. HILLIARD, and Mr. A. COLEMAN seem likely to supplant to a great extent the use of ether for dental operations. A smaller number of deaths has been recorded from chloroform used as an anæsthetic in dental practice. This is satisfactory and it is to be hoped that in the near future its use will be abandoned except under very exceptional circumstances.

The British Dental Association has continued to exert its beneficial influence on the profession and also on the public. The annual meeting at Bath was most successful, the papers read and demonstrations given being interesting and valuable. Under the name of "South Wales and Monmouthshire" a new branch has been added and the quite recently formed School Dentists' Society may be also regarded as an offshoot of the Association.

Fair activity has marked the dental literary world. The fifth edition of "Tomes's Dental Anatomy" has appeared and an excellent little work on Dental Metallurgy by Mr. ERNEST A. SMITH has been published. Mr. E. W. ROUGHTON has written a useful manual on Oral Surgery, while Dr. G. BLACK'S well-known work on the Human Teeth has reached a further edition. Other books worthy of mention are "L'Art Dentaire en Médecine Légale," by Dr. OSCAR AMÆDO and Dr. W. C. BARRETT'S "Oral Pathology and Practice."

An interesting event in the social world has been the golden wedding of Sir EDWIN and Lady SAUNDERS and the occasion was taken by a few old friends for presenting an address in remembrance of the happy occasion.

The death roll is happily a small one. It includes Mr. SIDNEY WORMALD, one of the pioneers of dental reform, Mr. J. MAIN NICOL of Leeds, and Mr. MCADAM of Hereford.

Biology and Physiology.

The subjects of Biology and Physiology have been prosecuted with unabated ardour by a thoughtful band of men, one of the most conspicuous of whom—M. MAREY—has in an important memoir read before the French Academy of Sciences drawn attention to the necessity which is daily becoming more urgent of the adoption of some standard of excellence in the several instruments which are in common use in the laboratory. Many prolonged series of experiments have proved almost valueless, especially in those where graphic curves are represented owing to the unreliability of the apparatus employed. Such records are worse than

Digitized by Google

useless since they encumber the pages of journals with erroneous data which cannot be distinguished from those which are exact and at the same time constitute fruitful sources of waste of time, temper, and work. M. MAREY hints his regret that there is no common language in use amongst men of science, meaning probably that his own language is that which is best adapted to be a common medium of intercourse; but with the rival claims of English and German in the immense scientific literature they represent there would appear to be little chance that French would be accepted, clear and precise as it undoubtedly is. M. PERRIER in another carefully considered memoir read before the same distinguished body discusses the always interesting subject of the origin of the Vertebrata, and whilst on various grounds rejecting the Tunicate origin advocated by Professor HAECKEL, the descent through the balanoglossus maintained by Mr. BATESON, that through the crustacea by Dr. GASKELL, that through the arachnida by Dr. PATTEN, and others, holds that vertebrates are descended from the annelida through the amphioxus. The counter and well-maintained arguments of Dr. WALTER GASKELL in favour of his own views on this subject may be read in the April number of the *Journal of Anatomy and Physiology* for this year.

The Roentgen rays, as was to be expected, have been utilised in the service of anatomy. Both Mr. W. S. HAUGHTON and Mr. HAROLD STILES have taken instructive skiagraphs after injection of the blood-vessels in which, owing to the opacity of mercury to these rays, the position, and subdivisions of the arteries are rendered very conspicuous.

The Anatomical Society of Great Britain and Ireland has done good work by circulating amongst the teachers of anatomy a series of questions and comparing or tabulating the answers, too few, unfortunately, which have been returned. Some very useful facts have been thus ascertained which would probably otherwise have been lost. For example, to the question of the frequency of an opening between the right and left auricles at the seat of the fœtal foramen ovale statements of 399 observations were received of which it must be said to his credit that Dr. SEQUEIRA, the medical registrar of the London Hospital, contributed no less than 188; the collective answers showed that the defect exists to a variable extent in one out of every four persons examined and rather more frequently in females than in males.

The chemical side of physiology is being actively pursued by many chemists as the multitude of articles in HOPPE-SEYLER'S *Zeitschrift für Physiologische Chemie* and other journals sufficiently testifies. Such difficult subjects as the constitution of the simplest proteids, the products of disintegration of albumin in plants and in animals, the nature of the albuminous constituents of hæmoglobin, the formation of urea in the liver, the generation of fat from sugar in the animal body, and the like, are being daily attacked by competent men from whose researches it may reasonably be hoped that a clearer insight into the more recondite processes of metabolism than we at present possess will in due time be acquired.

The same may be said of the other great support of physiology—microscopic work. The beautiful execution of many of the plates in the *Quarterly Journal of Microscopical Science* and in the *Archiv für Mikroscopische Anatomie*—as, for example, those illustrating Mr. MINCHIN'S Memoir on Ascons and Mr. MORRIS'S Molluscs of the Great African Lakes and those of Dr. KOSTANECKI on the Fertilisation of the Ovum of Myzostoma, of Dr. DOGIEL on the Sensory Nerve-endings in the Heart and Blood-vessels of Mammals, and of Dr. FRIEDMANN on the Anatomy and Physiology of the Male Sexual Organs of Man with quadruple staining—leave little to be desired and are not only instructive in showing what excellent results have been obtained, but are suggestive of vast fields of research which have been as yet scarcely more than entered. A useful collection of references to the original papers describing upwards of 100 dyes is given in the *Archiv für Mikroscopische Anatomie* by Dr. K. TELLYESNICKI, and Dr. JOSEPH S. BOLTON gives the results of a searching examination into the nature of the Weigert-Pal method of staining. The chrome-silver method is strongly recommended by Mr. W. HUNTER of Aberdeen for the demonstration of nerve-cells.

The histology of the animal cell has received much attention. Dr. A. KOLOSSOW, by using a mixture of osmic acid and uranium nitrate as a fixative and employing various dyes, has established the existence of connecting processes extending between the protoplasmic contents of many forms of cell. The processes are generally very numerous and appear to be subservient to the conduction of impulses and of nutrient material. Such processes occur between the cells of the liver, pancreas, testis, ovary, thyroid body and other organs, and his observations have been repeated, confirmed, and extended by Mr. WALTER GARDINER. A continuity of living material is thus established not only in the several parts of the same tissue but of contiguous organs throughout the body and serves in some degree to explain the secondary effects which are exhibited by parts far removed from the primary lesion. The great complexity of the internal structure of the animal cell is also being rendered more apparent by the methods of treble and quadruple staining to which allusion has just been made. Dr. HANS HELD has given beautiful illustrations of this complexity in nerve cells and Dr. GUSTAV SCHLATER in the cells of the liver, the several parts being rendered conspicuous by their differing affinity for different dyes.

The chemistry and histology of the thymus, thyroid, parathyroid, and suprarenal bodies, with in some cases the effects of the intravenous injection of their watery extracts, have been carefully studied. Dr. P. LANGLOIS found that the suprarenal extract injected into the veins of rabbit and dogs disappears from the arterial blood in less than three minutes, the augmented blood-pressure returning to the normal and the liver playing the chief part in its destruction. Mr. VINCENT found that the watery extract of 60 grammes of fresh adrenals subcutaneously injected into dogs first excited, then paralysed, and finally killed them, with great fall of temperature. Dr. BORDIER, experimenting on rabbits, observed after injection of the extract of the adrenals rise of blood-pressure, slowness of pulse, and then arrhythmia lasting for half an hour. Several observers have called attention to the absence of any similar effects from the injection of the extracts of brain, muscle, liver, spleen, or kidney. A statement has recently been made by Dr. CH. BOUCHARD that both in man and the dog under certain conditions

Digitized by Google

increase of weight may occur without the ingestion of food. As much as 600 grains or considerably more than an ounce can thus be gained in the course of an hour. The fact is not quite so isolated as might appear at first sight, for jockeys in training have been known to increase in weight to a noticeable extent after the consumption of a little wine and some animals maintain their weight during hibernation. Dr. BOUCHARD'S experiments demonstrate that the increase in weight is due to the absorption or retention of oxygen in the system and this he considers to be associated with the imperfect oxidation of fat and the formation of glycogen. M. BERTHELOT, an accomplished chemist, sees difficulties in this view and admitting the fact attributes it to the partial oxidation of albuminoid bodies with formation of special products. In experiments on the movements of the stomach as seen by the cathodic rays MM. ROUX and VON BALTHAZARD found that in man, the dog, and the frog alike, when the stomach is about to evacuate its contents, the contraction begins about the middle of the great curvature, the wave passing rapidly towards the pylorus and this is succeeded by another deep depression, so that a kind of pre-pyloric antrum is formed. GRÜTZNER has demonstrated that fluids and solid particles, such as lycopodium spores, introduced into the rectum may wander upwards and may even reach the stomach in man and mammals. MM. DASTRE and FLORESCO, as the result of many analyses, show that the liver is the ferruginous organ *par excellence* in the invertebrata, though in vertebrata iron is certainly a constituent of the blood and of the splenic tissue. Dr. AITCHISON ROBERTSON has made an experimental inquiry into the salivary digestion of starch in simple and mixed diets and his experiments show clearly the deleterious effects of wines and spirits on the process. WEISS, supporting the statements of SEEGEN, shows that the minced liver of the rabbit is capable of forming sugar out of fat and the fatty acids. MM. KOLISCH and STEJSKAL find that the jecorin discovered by DRECHSEL very easily splits off a molecule of sugar and that this is a process which is actively taking place in diabetes, the jecorin probably existing in the blood in some kind of combination with albumin.

The destruction of some kinds of sugar when injected into the blood in 10 per cent. solutions is swift and complete whilst others when thus introduced into the system seem to be capable of resisting disintegration. Thus in the experiments of VOIT the monosaccharides grape sugar, sorbinose, and arabinose were rapidly broken up and in the case of grape sugar as much as 100 grammes could be injected with the re-appearance of less than 3 per cent. in the urine. On the contrary, with the disaccharides cane and milk sugar nearly the whole quantity injected was eliminated by the kidneys. Yet the disaccharides maltose and trehalose were largely destroyed. The trisaccharide raffinose was used up to the extent of 35 per cent., whilst the polysaccharide glycogen was completely destroyed.

The subject of the nervous system has been worked at by Dr. BURDON SANDERSON who has studied the electrical response to stimulation of muscle; by Dr. J. BERNSTEIN, S. AMAYA of Tokio, and Dr. F. SCHENK who have investigated the subject of negative variation of the nerve current under different circumstances; by Dr. F. B. HOFMANN who has described the influence of the vagus upon the heart; by Mr. B. T. TEBBS and Dr. PAUL MANS who give the innervation of the heart and of the aorta and intercostal arteries; by Dr. OTTO WEISS who has experimented on the excitability of a nerve in its course, showing that the excitability remains the same throughout its whole length; and by Dr. E. STEINACH whose conclusions have been corroborated by Dr. SZYMANOWSKI and are to the effect that the posterior roots of the spinal nerves contain viscero-motor fibres. Mr. BISHOP HARMAN as the result of numerous dissections has demonstrated that the caudal limit of the lumbar efferent visceral nerves in man is at the level of the second lumbar nerve. The insular district of the cerebral cortex in man and the man-like apes has been an object of special study by Professor D. J. CUNNINGHAM of Dublin, and Dr. F. W. EURICH has written a good article on the comparative anatomy of the neuroglia. The subject of muscle has been elucidated by Mr. PARSONS who delivered a course of lectures at the Royal College of Surgeons of England on the muscles of animals with special relation to human myology; by Dr. TAIT MACKENZIE in his article on natural selection as shown in the typical speed skater in the *Journal of Anatomy and Physiology*, which is illustrated by photographs of the professional champion, J. NILLSON, an American of Swedish parentage, of J. JOHNSON, late professional champion, and of the amateur champion, J. K. MCCULLOCH. A new theory of muscular contraction has been advanced by Mr. W. MCDOUGALL which is to the effect that contraction is due to the elimination of lactic acid in the fluid contents of the sarcomeres which occasions the passage of fluid into the sarcomeres from the sarcoplasm.

The mode in which experimental physiology may correct the impressions derived from clinical observation is well shown in the explanation it affords of the phenomena of incontinence of urine and fæces, which have been generally regarded as indicative of destructive lesion of the lumbar region of the spinal cord; but MM. ARLOING and CHANTRE have removed the whole lumbar segment of the cord in dogs, with the result that in the course of a short time the animals recovered the power of retaining and of evacuating at will, though, perhaps, not completely the contents of the rectum and bladder. They attribute this remarkable circumstance to the elasticity of the sphincters which they have demonstrated to be fully capable of effecting the retention of these excreta. Hence, when incontinence occurs there is reason for believing that some stimulation of the expulsive agencies is being exercised. They found also that unilateral section of the nerves to the sphincters was quite without effect.

The observations of several physiologists seem to show that the fæces do not consist in more than a small proportion of the remains and indigestible residue of the food, but that they are chiefly the products of intestinal secretion and excretion. Thus M. KERMAUNER has shown that when meat is ingested in the adult only a very small proportion is discharged in the fæces, whilst the total nitrogen excreted is much larger, varying from 4 per cent. to 5·5 per cent., and both PRAUSNITZ and TSÜBOI have arrived at the same conclusion from their independently conducted experiments.

Residence in high altitudes being constantly recommended for patients suffering from anæmia it may be worth noting that the benefit obtained is apparently not owing to any increase in the amount of hæmoglobin, for in some experiments made by Dr. P. GIACOSA on rabbits, dogs, and himself during a residence at heights of about 8000 and 15,000 ft., though variations occurred at intervals no increase was observed in the quantity of hæmoglobin contained in the blood.

Amongst the books which have been published in the course of the year attention may be called to "The Text-book of Physiology," by Professor E. A. SCHÄFER, aided by several distinguished collaborators; to "The Text-book of Zoology," by Dr. T. JEFFERY PARKER and Dr. WILLIAM A. HASWELL; to the "Anatomie du Système Nerveux de l'Homme," by A. VAN GEHUCHTEN; and also to the new edition of STEWART'S "Human Physiology"; to the successive parts of the fine "Dictionnaire de Physiologie," by RICHET and others; to the first part of DOYON and MORAT'S "Traité de Physiologie," embracing the subjects of nutrition and calorification; and to STÖHR'S "Text-book of Histology," translated by Dr. ALFRED SCHAPER of Boston, U.S.A.

Anæsthetics.

The increased interest which has of late years been taken in the study of anæsthetics has during 1898 been more than maintained if we may judge by the large number of papers published and of researches undertaken in elucidation of the subject. Abroad especial attention has been directed towards means whereby local as opposed to general anæsthesia can be effectually obtained. In Professor SCHLEICH'S infiltration method the tissues operated upon are made insensitive by injecting a highly diluted solution of cocaine in normal saline. The injection, made first endermically, subsequently hypodermically, and eventually into the deeper structures, produces an œdematous and anæsthetic state of the tissues acted upon. The nerve endings become anæsthetised and as long as the effect lasts the parts remain insensitive. The initial pain of the first few punctures is removed in some cases by freezing the skin and in others by painting with a solution of cocaine, but DREYFUS[1] has used orthoform after infiltration as it tends to intensify and prolong the anæsthesia. The plan of SCHLEICH has now been employed for both minor and major operations, many of the latter of the first magnitude. As pointed out by KRECKE, however, the method has its limits. In the first place the patient is not always able to maintain his calm self-control throughout a prolonged operation, even although actual pain is absent. The tissues when infiltrated lose much of their natural appearance, and it is not easy to decide the line of demarcation between disease and health. The most scrupulous care is requisite to sterilise the solutions employed and to avoid forcing *materies morbi* from the region infiltrated into the subjacent zone. TITO COSTA, who has employed the Schleich plan, finds heated solutions act far more rapidly than if injection is made of cold solutions. During the year the infiltration methods, both that of SCHLEICH and that of RECLUS, have been modified by the use of other anæsthetics than cocaine. Thus tropacocaine and eucaine with and without minute quantities of morphine have been tried and found successful. Orthoform, referred to above, has found some favour. Its insolubility restricts its use save as a powder, although HIRSCHBRUCK has used it for injection, employing a 3 per cent. strength suspended in water.

The employment of nitrous oxide in the minor operations of surgery, excepting in dental practice, has never been extensive, probably owing to the evanescent and restless character of the narcosis it produces. These disadvantages have been in some way removed during the past few years. Within the last year methods, or perhaps more accurately variants upon older methods, have been introduced whereby nitrous oxide given alone or mixed with definite proportions of oxygen can be given for prolonged periods even although the mouth be the seat of the operation. Thus Mr. ALFRED COLEMAN covers the mouth and gives the gas solely through a cap which fits over the nose, Mr. HARVEY HILLIARD relies upon a nasal catheter for maintaining anæsthesia after the usual method of induction, while Mr. COXON and Mr. MACCARDIE warm the gas-supply and maintain the anæsthesia after removal of the face-piece by means of a buccal tube which conducts gas into the air-passages. The use of nitrous oxide with oxygen for operations lasting for periods of twenty minutes or more has received some attention, and it is claimed that the plan possesses special advantages over the use of the alcoholic narcotics.

The mortality under chloroform and the frequent pulmonary troubles following ether led SCHLEICH to attempt to obtain an anæsthetic with a boiling-point which was approximately of blood temperature so as to enter and leave the lungs without, on the one hand, accumulating in the circulation or, on the other hand, leaving the tissues still sensitive. With this view he employed a mixture of sulphuric ether diluted with petroleum ether, and chloroform in three proportions. The solutions so arrived at had definite boiling-points of 38°, 40°, and 42° C. and were to be used respectively for slight, medium, or deep anæsthesia. SCHLEICH himself, WILLY MEYER, MADURO, GARRIQUES, EMIL MAYER, and others affirm that perfect anæsthesia resulted from such solutions, while no after-effects were produced even in patients the subjects of heart, kidney, or pulmonary disease. RODMAN, however, after a prolonged use of these solutions, came to an opposite conclusion. He not only found heart failure, and renal and pulmonary complications accompany their use, but averred that the sickness, headache, &c., during recovery were as bad as with ether or chloroform. The valuable tables collected by GURLT, dealing with the mortality under anæsthetics, show curious figures which of course refer only to Germany. It is still a reproach to Great Britain that no general statistical record is kept of the enormous number of anæsthetics given in the United Kingdom. The statistics of GURLT now extend back to 1891 and show from 1895-97 a record of 27,025 cases of chloroform narcosis with 29 deaths, 19,875 cases of ether inhalation with 3 deaths, and 4927 cases of Billroth's mixture. In the period 1891 to 1897 the death-rate is 1 in 2039 for chloroform, 1 in 5000 for ether, 1 in 5228 for bromide of ethyl,

[1] Münchener Medicinische Wochenschrift, p. 527.

Digitized by Google

1 in 7594 for the mixture of chloroform and ether, and 1 in 213 for pental. He notes that the deaths due to chloroform are annually increasing and are mainly due to circulatory failure, while fatalities from ether are chiefly due to pneumonia after the operation. Italy returns a record of 53,972 cases of chloroform inhalation with 13 deaths and of 1 death in 2802 cases in which cocaine was used. These statistics include two years. Some important work in the field of the physiology of anæsthesia has been done during the year. Two observers, Dr. W. H. THOMSON and Dr. R. C. KEMP, have shown that ether is distinctly more dangerous to the epithelium lining the glomeruli of the kidneys of dogs than is chloroform, although ether is markedly less liable to lower the blood-pressure. Their examination of SCHLEICH'S mixtures referred to above and the A.C.E. mixture lead them to consider such mixtures in no way safer as regards the kidneys and circulation than ether or chloroform. Their results in the case of ether showing rapidly produced albuminuria and suppression of urine are not borne out by clinical investigations. LEGRAIN examined the urine of 54 persons who took chloroform and he found 10 cases of albuminuria with 12 out of 41 cases of etherisation. His experiments on dogs gave similar results and led him to believe that chloroform produced more lasting effects upon the renal structures.

PARASPORO'S research on the results following the repeated daily inhalation of chloroform or ether by dogs is one of importance as showing that parenchymatous degeneration and necrotic processes follow the prolonged administration of these narcotics. These experiments appear to have a close connexion with those of THIEM and FISCHER, who found that fatty degeneration followed chloroformisation. It is at least suggestive that DESGRÈS and NICLOUX found that potassium salts or alkalies in the presence of chloroform lead to liberation of carbon monoxide and, further, that in alkaline blood a like decomposition takes place. The fact that cholemia has followed and has proved fatal after chloroformisation if not coincidental is at least worthy of note, as CHIARLEONI has pointed out. The râles occurring during and after ether inhalation are commonly imputed to bronchitis. In contravention of this HÖLSCHER[2] has undertaken experiments which lead him to believe that ether does not act as an irritant to the mucous membrane of the respiratory tract. The râles are due at first to aspiration of saliva and mucus from the mouth, due to local irritation, into the trachea and subsequent bronchial trouble is in its turn due to further aspiration of these secretions into the bronchi. Thus if buccal secretions are excluded ether will cause no bronchitis. It can hardly be said that the vexed question of the action of chloroform upon the organism has been settled. The researches of WALLER upon nerve structure have taught us that nerve like other protoplasm is harder to kill with ether than with chloroform, at least at the time of administration. No doubt now exists that chloroform will kill under any circumstances if a large enough dose enters the circulation, whether it be at one time, as in the case published by Lieutenant-Colonel LAWRIE, R.A.M.C., in which the patient took an overdose during struggling and but for the prompt action of the surgeon might have died, or by slow accumulation in the blood. Equally certain is it that the blood-pressure falls under chloroform and that this is a source of danger, since the peril lies not in whether more chloroform is then taken in but in the quantity of the anæsthetic already in the blood. HILL'S researches pursued and confirmed during the year appear to prove this. WOOD has already pointed out that all the blood pressure tracings taken during chloroformisation have shown severe falls of pressure. The respiration, he urges, fails before the heart because cerebral anæmia is the first factor in the onset of this toxæmia; the coronary circulation, being at a lower level, proceeds for some seconds later, due to its more advantageous position.

Dr. BOWLES, whose papers on Resuscitation have thrown so much light on the subject, has again pointed out that the Sylvester method of artificial respiration is not the one which gives the best means of ventilating the lungs and removing air saturated with chloroform. Dealing with the dangers of impure anæsthetics it has been shown that spasm during anæsthetisation as well as cough and bronchitis may and do follow the respiring of impure chloroform. During the past year the matter has been painfully emphasised by the report of more than one death from inhaling chloroform the vapour of which had escaped into a room where lamps were alight. The carbonyl chloride formed, which splits up into carbonic and hydrochloric acids in moist air, has been shown by Dr. SEBASTIANO FAMULARI[3] to be extremely dangerous when inhaled. RAMSAY has further pointed out before the Society of Anæsthetists of London that carbonyl chloride is formed when chloroform is exposed to light in the presence of air. The paper of Dr. FAMULARI enters very fully into the chemistry of the matter.

Prophylaxis against accidents under and consequent upon anæsthesia has received much attention and various fresh agents have been suggested for use in chloroform toxæmia as correcting the effects on the respiration and blood-pressure. Hydrocyanic acid has been recommended as a direct stimulant to respiration by Professor HOBDAY, and MAGNKOWSKY has resorted to freshly prepared and sterilised suprarenal extract as a powerful circulatory stimulant, although from its very power it is one to be used with discretion. HENSEN'S researches upon uterine contractions under anæsthetics favour ether, but our space does not permit more than passing mention of his important communication.

Among the publications dealing with anæsthetics issued during the year may be mentioned the following:—H. Laing Gordon: Sir James Young Simpson and Chloroform. Transactions of the Society of Anæsthetists, London. Briegleb: Die Schleich'sche Infiltrations-Anästhesie und der practische Arzt (*Therapeutisches Monatsheft*, Berlin). Für Schleich? (*Medicinisch-Chirurgisches Centralblatt*, Wien). Grube: Zur Lehre von der Chloroform-Narkose (*Archiv für Klinische Chirurgie*, Berlin). Honigmann: Zur Lokalanästhesie (*Centralblatt für Chirurgie*, Leipzig). Vidal: Influence des Inhalations chloroformiques sur la Résistance de l'Organisme aux Infections (Compte rendu de la

[2] Archiv für Klinische Chirurgie, Band lvii.

Société de Biologie, Paris); and Influence des Inhalations chloroformiques sur les Phénomènes chimiques de l'Organisme (Physiologie. Travaux du Laboratoire de C. Richet, Paris). Hänkel: Handbuch der Inhalations-Anästhetica (Leipzig). Berdach: Beitrag zur Anwendung concentrirter Cocain-Lösungen (*Wiener Klinische Wochenschrift*). Bouchard: De l'Anesthésie par l'Éther (*Journal de Médecine de Paris*). Kinscherf: Die kurze Aether-Narkose (*Vereinsblatt für Pfälzer Aerzte*, Frankenthal). De Saint Martin: Les Inhalations de Chloroforme, déterminent-elles la Production d'Oxyde de Carbone dans le Sang? (Compte rendu de l'Académie des Sciences, Paris). Sudeck: Ueber Lokalanästhesie (*Deutsche Medicinische Wochenschrift*, Leipzig). Strassmann: Der Tod durch Chloroform in gerichtsärztlicher Beziehung (Berliner Klinik). Müller: Anästhetika (Berlin). Chirvinski: Farm. Vestnik (Mosk.). Methane Products as Anæsthetics. Spellanzon: Della Chloronarcosi nei Cardiopatici (*Rivista Veneto di Scienza Medica*, Venice). Chiarleoni: Colemia da Cloroformio come Complicanza delle Celiotomie (*Chirurgia Moderna*, Pisa). Poroschin: Zur Frage über die pathologisch-anatomischen Veränderungen in durch Chloroform-Narkose bedingten Todesfällen (*Centralblatt für die Medicinischen Wissenschaften*, Berlin). Schleich: Schmerzlose Operationen vertliche Betäubung mit indifferenten Flüssigkeiten (Berlin). Hölscher: Experimentelle Untersuchungen über die Entstehung der Erkrankungen der Luftwege nach Aethernarkose (*Archiv für Klinische Chirurgie*, Berlin).

The Mirror of Hospital Practice.

Among the many interesting and instructive cases which have appeared during the past year in the Mirror of Hospital Practice there are probably none of more importance than those illustrating the present treatment of intussusception. Of all the forms of intestinal obstruction intussusception may be said to take the first place in order of frequency, for it occasions the obstruction in about one-third of the cases. A very slight knowledge of the pathological anatomy of the disease would suggest the advisability of attempting reduction by means of the injection of water or other liquid into the bowel, and the method has without doubt in numerous cases been followed by recovery, and it is equally true that inflation by air introduced sixty years ago by Mr. GORHAM has proved successful in many instances. But neither injection nor inflation is free from danger. The over-distended bowel has in several instances given way and death has resulted. These methods, moreover, by no means rarely fail; when the air- or water-pressure has been pushed to the limit of safety, or even beyond, the invaginated bowel still refuses to return. This will occasion no surprise to anyone who has experienced the difficulty which so often exists of reducing an intussusception after opening the abdomen. The only hope which then exists is to be found in a laparotomy; but can we wonder that a child—for 95 per cent. of these cases occur in children—who has for several, often many, hours been afflicted with so depressing a condition and who has then been subjected to a forcible distension of the large intestine fails to survive the added shock of an abdominal section? It is unreasonable to expect it, yet the chance of recovery would assuredly have been greater if no inflation had preceded the laparotomy. It must further be borne in mind that no intussusception which is entirely confined to the small intestine can ever be benefited in the slightest degree by distension of the colon. To us the conclusion to be drawn appears inevitable. Every case of intussusception should undergo a primary laparotomy—that is to say, no injection, inflation, or manipulation should precede the opening of the abdominal cavity. The earlier the operation the better will be the prognosis, for the longer the duration of the intussusception before operative interference the greater will be the mortality. In comparing the statistics of inflation with those of intussusception we must not take the figures of those who always inflate before operating, for then only the more severe cases will have been operated on and the mortality will assuredly be worse in cases operated on than in those which were treated only by inflation. The statistics which should be compared are those relating to the cases which were treated by distension on the one hand and those in which a primary laparotomy was performed on the other. The results even now are good and they will improve when the general public appreciate more fully the great dangers of intussusception. Of the 6 cases of this condition which we have recorded in the Mirror during the year 5 patients recovered and 1 died, but in the fatal case the death occurred within twenty-four hours of the onset. In one of the successful cases the patient was only six months old.

We have been able to publish 5 cases in which a laparotomy was performed for perforation of a gastric ulcer. Four of these patients recovered and only 1 died. For recovery to occur after operation for this severe lesion the most essential condition is that not many hours should have elapsed between the perforation and the laparotomy: it may fairly be said that the probability of recovery if more than twenty-four hours intervene is very small indeed. In one of the successful cases 2 perforations were discovered.

Up to a very recent date a large class of cases was utterly beyond either medical or surgical skill: the patients were those in whom septic micro-organisms, especially streptococci, had passed into the blood-stream — cases of true septicæmia. None of the usual antiseptics can be of any use; even if the original wound might be made completely aseptic, the germs which are already absorbed are fully capable of causing death. So short a period of time has elapsed since anti-streptococcic serum was introduced that it is not possible to speak definitely on its value. There are several difficulties in the way. In the first place, only those cases should be considered in which bacteriological proof was obtained that the streptococcus was present in the blood, and, in the second place, the serums in use differ very widely in their anti-streptococcic powers. We have recorded three cases during the year in which the serum was employed. In one of the cases erysipelas was present, and with it was some acute endocarditis; after the injection the temperature fell rapidly and the endocardial signs greatly diminished. In the second case puerperal septicæmia was present and bacteriological examination of the blood and

Digitized by Google

urine proved the presence of streptococci, and the recovery seemed almost certainly to be due to the serum. Unfortunately in this case severe symptoms were apparently produced by some of the injections and the serum was found to contain living staphylococci. In the third case much improvement was apparently due to the serum. We must hope in the future for more bacteriological confirmation of the streptococcic origin of the septic symptoms present before this treatment can be put on a sure footing.

The closely allied subject of the employment of antitoxic serum in tetanus has been illustrated by 3 cases in the Mirror. In the laboratory tetanus antitoxin has a very definite action in checking the progress of the disease in animals, but in man the results have hardly come up to what we were apparently justified in expecting; yet we must not relinquish this mode of treatment, for it is undoubtedly of value and we may look for better results when the preparations of the antitoxin are more uniform in strength. It can hardly be said at present that the general mortality from tetanus has been materially lowered by the serum treatment. It seems, however, certain that the earlier the antitoxin is injected the more efficacious it is. We have printed two cases of great interest in which foreign bodies which had been swallowed were removed from the stomach. In the first case, which was under the care of Mr. JOHN MORGAN, a young man had swallowed numerous metallic bodies during an attack of acute mania; some had been passed with the motions, but epigastric pain and the formation of a swelling in the same region pointed to some complication resulting from the continued residence of one of the foreign bodies in the stomach. A skiagram gave no indication of the presence of any metallic substance. At the operation, however, a piece of steel stay-busk about 4 in. long was discovered immediately beneath the abdominal wall lying in a cavity formed by peritoneal adhesions. The absence of any sign on the skiagram is probably to be explained by the fact that the piece of steel was vertical to the photographic plate. In the second case, which was under the care of Dr. PERCY POTTER, the presence and position of the foreign body, a steel button-hook, were very definitely shown by the Roentgen ray picture, and it was easily removed by a gastrotomy. In both cases the patients recovered.

Perhaps the most dangerous complication of an operation for the removal of an ovarian cyst is the tearing of a piece of the bowel in separating an adhesion. In two instances under the care of Dr. LEWERS which we recorded this serious accident happened, but the cases served well to illustrate the fact that prompt recognition and careful treatment of the lesion suffice to lead to an uneventful recovery.

We know so little of the real cause of the formation of cheloid that the case under the care of Mr. GOLDING-BIRD was of interest, and especially important was the fact, mentioned in his remarks on it, that in a district in British Central Africa every wound is likely to become the seat of cheloid. This evidence in favour of a special poison, probably microbic in nature, is very noteworthy.

Dr. WILLIAM DUNCAN described a unique case. A woman, thirty-three years of age, had had a vesico-uterine fistula for about six months and he determined to fix the vaginal portion of the posterior lip of the cervix into the opening in the bladder and thus close the fistula at the expense of diverting the uterine canal into the bladder. This operation was performed successfully and a month later both ovaries and tubes were removed. When she left the hospital three months after admission the patient was able to hold her urine for eight or nine hours and the vagina was quite free from moisture.

An interesting example of Richter's hernia, or partial enterocele, which was under the care of Mr. STANMORE BISHOP, was published. The constricted portion of bowel gave way into the scrotum but no peritonitis occurred beyond that required to fix the bowel in position. The operation performed to remedy the fæcal fistula which resulted was completely successful.

The general opinion of surgeons has always been decidedly opposed to simultaneous ligature of the popliteal artery and vein and the chance of gangrene has been considered to be so great that amputation at the knee-joint has been looked upon as a preferable operation. Still, a few cases have been recorded in which no gangrene followed the double ligature and we published two similar cases; in one under Mr. EDMUND OWEN'S care the vessels had been accidentally wounded; in the other Mr. G. P. NEWBOLT tied both vessels in order to cure an arterio-venous aneurysm which had formed. No gangrene followed in either instance. In all 17 cases have been recorded and in only one did gangrene result. Transperitoneal ligature of the iliac arteries is gradually becoming the operation which is to be preferred. This operation is already acknowledged to be the best in the case of the common and internal iliacs, but there is room for a little more difference of opinion with regard to the external iliac artery, though we believe that for this vessel also it will ultimately come to be the ordinary method. Mr. FREDERICK PAGE has recorded a case which illustrates well the simplicity of the operation. The value of intravenous injection of normal saline solution is generally appreciated nowadays and so much is this the case that transfusion of blood is hardly ever performed. A very striking example of the rapidly beneficial results of this operation is to be found in a case under Mr. BOYCE BARROW which we published. On one occasion five pints and on another two pints were injected with remarkable improvement in the general condition; in fact, at one time immediately before an injection the patient seemed to be moribund.

The Naval and Military Services.

The past year has not only been an eventful one as far as the naval and military services are concerned, but it has been crowded with incidents some of which are historical and destined to have a far-reaching tendency. If a country may be said to be blessed whose annals are inglorious there would be some difficulty in selecting one entitled to that blessing at the present time. We have been living amid wars and rumours of wars on all sides and the year that is past has been notable from the fact that it had no "silly season," for it was at the time when there is usually a dearth of exciting political intelligence that the journals of Europe, America, and the East were heavy-laden with news of grave and varied import. In India we have had a big war on the North-West frontier, in

Digitized by Google

addition to the continued and increased prevalence of plague with its serious effect on the commercial prosperity of that country and the grave risk of political disaffection on the part of the native population, to say nothing of the enormous amount of extra labour and responsibility these occurrences entailed upon all classes and not least upon the medical services of that country. Nor can it yet be said of India that there is any promise of "the land having rest" for some years to come. In Egypt we have had the Soudan Expedition, now happily terminated by the victories at Atbara and Omdurman and the annihilation of the Khalifa's cruel and oppressive rule. This was speedily followed by the Fashoda incident with its attendant complication with France. There have also been explorations, complications, and fighting in other parts of the African Continent, as well as at Crete and in China. The officials of the Foreign Office, the Admiralty, and the War Office have had ample employment, notwithstanding which, we are glad to say, the War Minister has found time to introduce a wise and comprehensive measure effecting the welding together of the Army Medical Service into the Royal Army Medical Corps, in addition to redressing a number of grievances of which the members of that branch of the Army Service legitimately complained. It was a happy inspiration of Lord LANSDOWNE to announce at the Lord Mayor's dinner to the medical profession in May last his intentions regarding the Army Medical Service and to foreshadow the Warrant in a handsome and outspoken speech appreciative of the services of army medical officers and those of the profession generally to the public service, and it is needless to add that the speech gave great and general satisfaction. Turning to other parts of the world we have had the Spanish-American war with its striking and dramatic incidents and results, the full effects of which have yet to be realised and harvested. That these will be for the good of humanity and the world at large cannot be doubted; and we have only to take account of the inimical feeling and even consternation with which the drawing together of the American and British nations is regarded by foreign Powers to see that they, at any rate, realise the meaning and import of such a combination. We heartily congratulate the United States on the successful termination of that war, believing as we do that its results will be favourable to the freedom of the oppressed and eventually turn out to be for the benefit of all concerned. The year 1898 is the most eventful to the American Republic since the end of its civil war. For the first time the United States Government finds itself face to face with the problem of dealing with foreign possessions outside its own continent. Considering that a commission is inquiring into the causes and extent of the alleged breakdown of the sanitary and medical arrangements of the late war, for which the United States was apparently unprepared, there is no need to dwell further upon the subject now; but we may add a word to the effect that it is only by the organisation and perfecting of all that appertains to a medical service in times of peace that successful results can be attained in time of war. There is no royal road to success in this respect as this and other countries have had to learn by bitter experiences in the field.

We have endeavoured to keep our readers *au courant* with the medical history of all the campaigns and expeditions in which this and other countries have been engaged. Our information in this respect, and especially in regard to the big and very difficult campaign against the frontier tribes on the North-West of India, has been, we believe, both full and reliable. As regards the Soudan it is worthy of record that Lord KITCHENER of KHARTOUM, in his military dispatch after Omdurman, spoke in the highest terms of commendation of the "unremitting energy, untiring zeal and devotion to their duty of the entire medical staff."

It has been our pride and satisfaction to chronicle in connexion with these campaigns the conduct and devotion of medical officers and the rewards which have been conferred upon a number of them for their gallantry and distinguished services in the face of the enemy. In these respects no branches of the naval and army services have done better, or have had a longer list of names mentioned in despatches or of Victoria Crosses and Distinguished Service Orders, than the various medical services. It was only the other day that Her Majesty added another to the list by conferring the docoration of the Victoria Cross on Surgeon W. J. MAILLARD, M.D., of the Royal Navy, for his conspicuous bravery displayed in September last during the outbreak at Candia.

During the year the autumn manœuvres have taken place on a far larger scale than has hitherto been the case. It is almost superfluous to remark that if the Royal Army Medical Corps is to be really effective it must rehearse in times of peace the duties which it will have to put in practice in the field during war and these military manœuvres afford the only opportunity of doing this.

Nor should it be forgotten that the QUEEN, in conformity with the compassionate interest which HER MAJESTY has always manifested in the distress of any of her subjects, has exhibited a lively sympathy with her sick and wounded soldiers invalided from the campaigns on the north-west of India and from the Nile Expeditionary Force in Egypt by repeated visits to Netley during the past year.

The Warrant of 1898 constituting the Royal Army Medical Corps appeared in THE LANCET of July 9th last. It is a satisfactory warrant and we have no hesitation in saying that the Army holds out a good prospect for medical candidates for the Royal Army Medical Corps. We have so recently dealt with the memorial of the Royal College of Surgeons of Edinburgh to Lord LANSDOWNE regarding the changes which might still be advantageously made in the regulations for competitive entrance examination into the corps that it is needless to refer to the matter beyond saying that we agree with the College in their opinion that too much importance is attached in those regulations to elementary subjects and too little to the practical and clinical work which now occupies the latter years of professional study. That some change will hereafter be made in this direction we do not doubt. We also hope to see some alterations carried out in regard to the present rates of pay and allowances of officers of the Royal Army Medical Corps serving in India.

With regard to the changes in the services, the Naval Medical Department has during the year had a new Director-General in the person of Sir HENRY F. NORBURY, K.C.B. Surgeon-General CLEGHORN having retired from the post

Digitized by Google

of Director-General of the Indian Medical Service and Sanitary Commissioner with the Government of India has been succeeded in these appointments by Surgeon-General R. HARVEY, C.B. Surgeon-General A. A. GORE, Principal Medical Officer of Her Majesty's Forces in India, who retires this month, is to be succeeded by Surgeon-General W. TAYLOR, C.B., who was the Principal Medical Officer of the Nile Military Expedition during the late campaign.

The Indian Medical Service has undertaken and discharged a large amount of work and responsibility during the epidemic of plague in that country, in addition to its labours in the field in connexion with the expeditions on the North-west frontier, where several of the medical officers greatly distinguished themselves and all did excellent work. The new Army Warrant has, of course, been made applicable to this service as regards the rank and titles of medical officers, but its name—Indian Medical Service—has been retained, carrying with it as it does so many honourable traditions.

We regret to add that death has as usual thinned the ranks of the different medical services. When death comes to men who have done their work and retired this is neither unexpected nor to be lamented; it is when it cuts off relatively young and promising men while their careers are still unfulfilled that death is so regretful and occasionally so pathetic. It would be impossible as well as wearisome to enumerate all our losses in this direction. But we may mention the names of Inspector-General T. R. PICKTHORN, Deputy-Inspector-General LEONARD LUCAS, Deputy-Inspector-General G. J. KELLIE, and Deputy-Inspector-General E. W. BAWTREE, Fleet-Surgeon C. KNOX ORD and Fleet-Surgeon C. A. MACAULAY of the Naval Medical Service; of Surgeon-General MACLEAN, C.B., LL.D., M.D. Edin., whose name was so long associated with the Army Medical School at Netley; of Inspector-General JOHN MURRAY; of Deputy-Surgeon-General PARTRIDGE, who was an excellent surgeon and did good work at the College Hospital in Calcutta; and of Surgeon-General F. M. CLIFFORD and Surgeon-General W. JOHNSTON,—all of the Indian Medical Service. The Army Medical Service has lost during the year Surgeon-General S. CURRIE, C.B., Surgeon-General S. FULLER, Surgeon-General ALEXANDER SMITH, C.B., Surgeon-Major-General JAMES INKSON, and several medical officers of other ranks.

Chemistry.

Chemists this year would seem to have paused in their practical labours and to have rested awhile, so to speak, in order to ponder over the significance of the results which their arduous work has presented to the world during the last decade. This, at any rate, seems to have been the course adopted by that brilliant investigator, Sir WILLIAM CROOKES, who in his remarkable address at the meeting of the British Association at Bristol sounded a distinct note of concern as to the future of the world's wheat supply. He feared that the future demands of an ever-increasing population would sooner or later not be supplied by the ordinary methods of agriculture, the soil would be exhausted of its nitrogen, and he suggested that the teaching of the chemical laboratory would furnish the only means of escape. The question that confronts us is how to compensate for the exhaustion of the world's stock of fixed nitrogen, a matter in Sir WILLIAM CROOKES'S opinion of far greater importance than the exhaustion of British coal-fields. He has been therefore led to suggest that the nitrogen of the air should be turned to account by burning it into nitric acid by the agency of the electric discharge. This conversion might be effected, he thought, by the utilisation of some colossal natural force as by the falls of Niagara. On the other hand, those veteran agricultural chemists, Sir HENRY GILBERT and Sir JOHN LAWES, maintain that there is no ground for such fears. In their exhaustive experiments they have shown that the wheat plant can flourish on the land again and again without manuring, and they show that nitrate may be derived from the soil even at a depth of nearly 9 ft. There is little doubt that nature herself provides a means, though it be a slow process, of fertilising the land. Again, we know how certain plants are nourished by direct assimilation of free nitrogen through the nodules on the roots and probably by microscopic agencies. Chemistry in its relation to food supply would seem to be the subject also underlying the announcement made during the year by Dr. LILENFELD at the International Congress of Applied Chemistry at Vienna to the effect that he had discovered the synthesis of albumin. The announcement created considerable excitement in chemical and physiological circles, but was very generally discredited, we ourselves being amongst the incredulous. Nor has the subsequent publication of the results conveyed any assurance that the synthesis of either albumin or peptone has been accomplished. Still there can be little doubt that some progress in a very important direction has been made since probably the investigator has thrown further light on the constitution of those complex bodies, the proteids.

There has been a remarkable revival of the old theory of "vitalism" during the year and a very instructive discussion took place in the Chemical Section of the British Association for the Advancement of Science, the subject having been opened by Professor F. R. JAPP in a very scholarly address. It is well known that the majority of chemists hold that the synthesis and separation of optically active compounds have been effected without the intervention of life either directly or indirectly. Professor JAPP holds the contrary opinion and it would appear that another well-known chemist, Professor CRUM BROWN, partly shares in this belief, which amounts to the theory that a living organism exerts an action in separating, for instance, two kinds of crystals as in the classic and well-known experiments of PASTEUR on tartaric acid and racemic acid. It is curious that as the study of stereo-chemistry or structural chemistry has advanced it should induce chemists to revert to the old theory of "vitalism" which everybody had accepted as overthrown when WOHLER announced the synthesis of urea—a body which had been known formerly as exclusively the product of the living organism. The pursuit after new elements has proceeded apace, and investigators appear to hold the conviction that we have not exhausted the atmosphere of its list of elements. Professor RAMSAY now speaks of others in addition to argon, which he calls its companions—namely, krypton, neon, and xenon, all of which are spectroscopically distinct. That the spectroscope, however, may

Digitized by Google

lead into some curious errors of observation would seem to be the case according to an example which we recorded in THE LANCET a few weeks ago. It was announced from America that a new gas—etherion—had been discovered in the atmosphere which possessed physical properties, placing it more nearly than ever to the *materia prima* the protyle of CROOKES. Sir WILLIAM CROOKES, however, suggested that it was nothing more than very highly attenuated water vapour, and he quoted evidence which is certainly in favour of this view. Subsequent observations leave little room for doubt that aqueous vapour under a high degree of exhaustion was the "new gas." In our *résumé* last year of the chemical progress of 1897 we mentioned how an American investigator had convinced himself that he had found out a means of converting silver into gold. He claimed to have discovered how to utilise that force by which the transmutation of metals could be brought about. Sir WILLIAM CROOKES, we believe, has failed to accept this as an accomplished fact after careful inquiry, having had the opportunity of examining the details of the process and the materials employed.

The discovery of rare elements in the atmosphere may possess little significance in the ordinary affairs of life, but the importance of this line of research has become exceedingly great owing to the enormous advances which these discoveries have made in our knowledge of the composition and character of stars. Sir J. NORMAN LOCKYER finds that in the very hottest stars we deal almost exclusively with the gases hydrogen, helion, and doubtless others still unknown. At the next lowest temperatures these gases are replaced by metals in the state in which they are observed in our laboratories when the most powerful jar spark is employed. At a lower temperature still the gases almost disappear entirely and the metals exist in the state produced by the electric arc. Thus it is possible to classify the stars into those which are getting hotter and those which are cooling. In this classification the spectroscope is the greatest help and the discovery of elements on this earth which were formerly known to exist only in the stars has materially aided in the work. The chemistry of the stars has thus become a new and possible source of fruitful study.

The year has been marked by the output of a smaller number of synthetic products although the investigating chemist has been very busily engaged in attacking the problem of the *constitution* and *structure* of compounds. We believe that this is a direction of research which, if pursued diligently, will add more materially than by paying attention merely to *composition* to our knowledge of the therapeutics of remedies and of the processes concerned in that mysterious chemical laboratory the human body.

Vaccination.

The year has been a most momentous one with regard to vaccination and its administration. The various points of interest may be most conveniently considered here in the order in which they present themselves in the Vaccination Act of 1898. As a result of the final report of the Royal Commission which had sat for seven years and had considered the subject from every possible aspect the Government concluded that fresh legislation was necessary. They accordingly introduced last session into the House of Commons a Bill which was the subject of lengthened discussion both in Parliament and in the country and which ultimately resolved itself into an Act differing in various important respects from the Bill as originally introduced.

The primary vaccination age limit.—The Bill proposed that the age limit for primary vaccination as required by the law should be extended from three months to twelve months. In the course of discussion, however, it was pointed out that owing to change of residence many children would be difficult to trace at the end of twelve months, especially in large towns, and the age of six months as in the Scottish Act was finally adopted. The change from three months to six months is advantageous in so far as it may diminish the sentimental objection which some parents have to submit their offspring to vaccination at a very early age and in so far also as it will render vaccination free from suspicion of being the cause of those infantile deaths which under the old age limit would have followed vaccination but which under the new age limit will precede vaccination. Section 1 (5) enacts that no regulation of any lying-in hospital or infirmary or other such institution shall interfere with the extension of the age limit for primary vaccination.

Domiciliary vaccination.—An important feature of the new measure is its introduction of domiciliary vaccination by public vaccinators in substitution for vaccination at public stations which has been the system in force under the Vaccination Acts up to the present time. Several advantages are claimed for the new procedure. Children will not be exposed to any risks from bad weather incident to their being carried to and from a public station for purposes both of vaccination and of subsequent inspection. Nor will they be exposed to any risk of infection from mingling with a gathering of many children at a public station. It is possible also that some parents who might refuse or neglect to bring their children to a public station may be willing to have them vaccinated at their own homes. The Act requires that when the child has reached the age of four months the public vaccinator of the district shall give to the parent or guardian at least twenty-four hours' notice of his domiciliary visit. By an Order made by the Local Government Board under the Act the vaccination officer must provide the public vaccinator periodically with lists of children aged four months at whose homes it will be his duty to call, and his visits must be made within a fortnight of his receiving each list. He is required to make one other visit during the second week and to make any additional visits which he may find necessary in any case.

Glycerinated calf-lymph.—Following the sections of the Act the next point to be noted is that the material to be used by the public vaccinator in his domiciliary vaccinations shall be "glycerinated calf-lymph or such other lymph as may be issued by the Local Government Board." This mention of glycerinated calf-lymph is of much importance. In the first place, it involves the discontinuance of humanised lymph. While the risks of humanised lymph were very trifling—were, indeed, so trifling that medical men have habitually used it in their own families—there is no doubt that, mainly as a result of elaborate exaggeration on the part of opponents of vaccination, these risks have bulked very considerably in the public mind. The substitution of calf-lymph should do much to allay these ill-founded fears

Digitized by Google

though it is a matter of course that strenuous efforts are being made by anti-vaccinationists to inflame and prejudice the public mind against the new system. Incidentally the use of calf-lymph means the discontinuance of the habit of opening the vesicles on a child's arm on the eighth day, and in so far as any risk, say, of the subsequent introduction of erysipelas has attached to this procedure such risk will disappear. It is not meant here that erysipelas will never again follow a vaccination, for under no system can parental carelessness be always and entirely freed from its own punishment. But the lymph to be used is not merely to be calf-lymph, it is to be glycerinated calf-lymph. To mix calf-lymph with glycerine is not a new thing and that fact has of late been largely advertised by opponents of vaccination. The essence of the new system consists in so conducting the treatment of the lymph with glycerine as to cause the destruction of extraneous organisms. Briefly stated this is accomplished by not merely mixing the lymph with glycerine, but by storing it in glycerine. The details of the process have been most carefully wrought out by Dr. MONCKTON COPEMAN. The additional words of the section of the new Act—namely, "or such other lymph as may be issued by the Local Government Board"—are evidently intended to cover the possibility of other means being introduced for bringing about the required result. It is most important that public and private vaccinators and makers of glycerinated lymph should recollect the fact just mentioned—namely, that the mere mixing of glycerine with lymph does not necessarily attain the desired end. Just as carbolic acid may be used without resulting in surgical antisepsis, so glycerine may be used without destroying all the organisms which ought to be destroyed.

Postponement of vaccination.—The Act adds to the conditions previously recognised by law as justifying the granting of a certificate for the postponement of vaccination. Section 1 (4) is partly as follows: "The public vaccinator shall not vaccinate a child if in his opinion the condition of the house in which it resides is such, or there is or has been such recent prevalence of infectious disease in the district, that it cannot be safely vaccinated ....." Under these circumstances not only is a certificate of postponement to be granted but the public vaccinator is to give notice to the medical officer of health for the district. This section is open to some difference of interpretation. It may be assumed that every public vaccinator would consider the existence of erysipelas in the dwelling a reason for postponement, but the question whether the prevalence, say, of whooping-cough in a neighbourhood would render the child's vaccination unsafe would have to be answered according to circumstances.

The "conscience clause."—Section 2 of the Act is popularly known as the "conscience clause" and has been a cause of more discussion than all its other provisions. The Bill originally proposed that not more than one or at the most two penalties should be inflicted with regard to any child. This provision was keenly debated in the Grand Committee but was retained by a narrow majority as against a proposal for a conscience clause. In the House of Commons on the report stage the Government yielded to what it was probably mistaken in believing to be the opinion of the House in favour of further relaxation to the extent of providing for the acceptance of the plea of conscientious objection as a means of relief from the infliction of even a single penalty. The House of Lords threw out this proposal and sent the Bill back to the Commons altered accordingly. In the Lower House the Government re-affirmed its new determination in favour of a conscience clause, and when the Bill again came before the Lords much public and professional interest was felt in the result. It was thought very likely that the clause would once more be rejected and this would have meant the withdrawal of the Bill, at least for the session. Lord LISTER, however, was in a position to make a most important announcement which was immediately afterwards officially confirmed on behalf of the Government and which had the effect of inducing the Lords to accept the conscience clause, though not even then by a very large majority. The announcement was that the Government would during the recess set itself to consider the preparation and introduction in the next session of Parliament of a Revaccination Bill. The conscience clause as it now stands in the Act is as follows:—

"Section 2—(1). No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1867 if within four months from the birth of the child he satisfies two justices or a stipendiary or metropolitan police magistrate in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child and within seven days thereafter delivers to the vaccination officer for the district a certificate by such justices or magistrate of such conscientious objection.

(2) This section shall come into operation on the passing of this Act, but in its application to a child born before the passing of this Act there shall be substituted for the period of four months from the birth of the child the period of four months from the passing of this Act.

The rest of the Act will come into operation on Jan. 1st, 1899, but it will be observed that the conscience clause came into operation from the date of the passing of the Act, so that already some experience has been gained regarding it. This experience has shown that, leaving aside the question of the desirability of having such a clause, the section is very vague and doubtful in meaning. Some justices of the peace have held that even if they are in a minority on the Bench any two of them can grant a certificate of exemption. The word "satisfies" in the section has evoked much diversity of opinion among magistrates. In some places all applicants have been put on oath; in others sworn testimony has been considered unnecessary. In some places applicants have been questioned with more or less detail as to the nature of their objection to vaccination; in others a mere statement of objection or the presentation of a printed declaration with the signature attached has been looked upon as sufficient. In some places the father of the child has been required to appear; in others the attendance of the mother has been accepted. In some places a birth certificate has been demanded in order to satisfy the Bench as to the age of the child; in others it has been held that no birth certificate is needed. In some places applicants have paid the fees for certificates exigible under the regulations of the court; in others applicants have refused to pay these fees and have in consequence gone away without certificates. Had the section been more

Digitized by Google

carefully considered no such crop of difficulties would have arisen regarding it. By sub-section (2), as above quoted, it will be observed that all children whose vaccination has been omitted in recent years come under the operation of the new Act and that where no certificate has been lodged by December 12th ("four months from the passing of this Act") the parent becomes liable to a penalty under the Act of 1867. The early months of 1899 should therefore witness some interesting proceedings, as it cannot be doubted that there has been failure to apply for certificates in the case of many children in various parts of the country. In THE LANCET we have held all through the course of the discussions which have taken place on this subject that it is not right to assume that everyone who is in favour of a conscience clause is opposed to vaccination or even that some who favour such a clause are anything less than hearty supporters of vaccination. The Royal Commission, which contained medical members such as Sir JAMES PAGET, Professor MICHAEL FOSTER, Mr. HUTCHINSON, and Sir W. GUYER HUNTER, and lay members like Lord HERSCHELL, the late Mr. MEADOWS WHITE, Q.C., Sir EDWIN GALSWORTHY, and others, reported strongly and unequivocally their belief in the value and essential importance of vaccination. At the same time they reported in favour of a conscience clause, and they did so believing that relaxation of the law might tend rather to the increase than to the diminution of vaccination. Looking to the fact that about a fourth of the boards of guardians in England had ceased to administer the law and that about a third of the children born last year remained unvaccinated, it is a mere misuse of language to speak of England as having been under a system of compulsory vaccination in recent years. It is true that there was on the statute book a penal law, but in many parts of the country it was not administered and in some places where it was administered the imposition of penalties did not procure vaccination. What exactly will be the effect of the new Act on the prevalence of vaccination it is not yet possible to say, but it must be recollected that the law is altered not merely with regard to its so-called compulsory provisions, and that some of the alterations, such as the adoption of a system of domiciliary vaccination and the use of glycerinated calf-lymph, may, taken together with the conscience clause, have the result of making vaccination more acceptable than before and of rendering organised opposition less effective and successful than it has been in the last few years. The new Act, however, remains in force for only five years and at the end of that period the whole subject must again come up for consideration by Parliament.

A Revaccination Bill.—It is of the utmost importance that the Government should now proceed to fulfil those promises regarding a Revaccination Bill by means of which they succeeded in passing the conscience clause through the House of Lords. If there should in this matter be any evidence or likelihood of delay it would be the duty of the medical profession to call immediate and emphatic attention to the subject and we have no doubt whatever that Lord LISTER, to whom the Government owes so much, would here lend his powerful aid.

Penalties.—In the discussion on the Bill previously to the adoption of the conscience clause considerable importance attached to the question of repeated penalties, and though it is now of much less moment the effect of Sections 3 and 4 may be noted. Where a parent has not taken advantage of the relief provided by Section 2 he may be prosecuted under Section 29 of the Vaccination Act of 1867. If a conviction is obtained under this section the new Act provides that an order under Section 31 of the Act of 1867 directing that a child be vaccinated shall not be made until the child has reached the age of four years, and that a single conviction under Section 31 will prevent any repetition of proceedings under that section. The effect will be that anti-vaccinationists who are obstinate enough to refuse the means of relief provided by Section 2 will be liable to one penalty when the unvaccinated child reaches the age of six months and to another penalty when it reaches the age of four years, after which there will be permanent release from the operation of the Acts. If owing to refusal to pay fines or costs imprisonment becomes necessary the prisoner will in future be treated as a first-class misdemeanant.

Public vaccinatorships.—The purpose of Section 6 of the new Act is to enable the Local Government Board to regulate the duties and remuneration of public vaccinators, whether appointed before or after the passing of the Act. It is under this section that the Board recently fixed the minimum scale of fees which has been the subject of so much discussion by boards of guardians and public vaccinators. It is only necessary to mention here that the minimum scale consists of a fee of 1*s.* in respect of the name of every child contained in lists to be periodically submitted by the vaccination officer to the public vaccinator for the purpose of being visited, and a fee of 5*s.* for every successful infantile vaccination, excepting in workhouses, where the minimum fee is 2*s.* 6*d.*, and for vaccination or revaccination of persons over fourteen years of age at the public vaccinator's consulting-rooms or elsewhere, for which also the minimum fee is 2*s.* 6*d.* In many places scales of payment considerably in excess of these minima have already been agreed upon by guardians and their public vaccinators.

Vaccination stations.—The Act further provides (in Section 7) that in exceptional circumstances, as where prevalence of small-pox is threatened, the Local Government Board may modify the requirements regarding domiciliary vaccination and may order the guardians to establish temporarily public vaccination stations which are otherwise to be abolished.

Hospital records.—In view of the wild allegations which have sometimes been made as to manipulation of the records of small-pox hospitals, the Act lays on all sanitary authorities the duty of keeping lists of small-pox cases treated in their hospitals, including a statement of their vaccinal condition on admission, and public access to these lists is to be allowed at all reasonable times.

The Act does not extend to Scotland or to Ireland.

As we have already indicated it is at present impossible to make a profit-and-loss estimate of the results of the new Vaccination Law. Excepting as regards the conscience clause the Act comes into operation only on Jan. 1st, 1899, and domiciliary vaccination in England is therefore as yet an untried experiment. Already the conscience clause has been construed so differently in different districts as to

Digitized by Google

show the need for its immediate amendment by Parliament, so that magistrates and the public generally may know what is really meant to be enacted. Where a father has had to leave his work in order to attend court and has there had to produce a child's birth certificate and to state on oath his conscientious objection to the vaccination of such child the test has had in it something of reality. Where no oath has been administered, where no birth certificate has been required, where the attendance of the father has been unnecessary, where the objector has been put to no trouble or inconvenience of any sort the clause in its operation has provided no test whatever between conscientious objection and mere indifference or laziness. For the working of the remainder of the Act it will be necessary to wait to see.

Public Health.

So far as can be judged from the vital statistics as yet available the year 1898 bids fair to turn out in the main a healthy one. Not only was the general rate of mortality below the average for the first two quarters of the year, but the same would have applied to the third quarter also had it not been for excess in death from one single disease affecting one age-period only. Subject to the same exception the death-rate from the zymotic group of diseases during the three quarters in question was also below the average for the past ten years. The exception has to do with diarrhœa which was essentially infantile in its incidence and which caused a considerable increase in death during the third quarter of the year. The rate of mortality under one year of age during that quarter showed an excess of 55 on every 1000 births beyond the average; the zymotic rate also exceeded the average, and the diarrhœa rate reached 2·85 per 1000 living, or 1·21 above the average for the preceding ten years. As is usually the case this excess coincided with a high temperature and a diminished rainfall. Thus during August the temperature on certain occasions reached 12° F. and in September 17·7° above the average, and the rainfall for the third quarter was nearly 5 in. below the average. The towns always suffer most under these circumtances, and amongst those which had the highest diarrhœa death-rates were Hull, Sunderland, Sheffield, Wolverhampton, Preston, and Salford. Notwithstanding the failure of a constant service of water in an important portion of the metropolis London as a whole finds no position of unenviable prominence in the Registrar-General's returns for the third quarter of the year as regards either diarrhœa or fever. The subject of a deficient water service was, however, one to which great prominence was given during the year and it was associated with an effort on the part of the Government to obtain both for water consumers and in some respects also for water companies more control than they now possess in the matter of protecting from pollution the sources of water which companies and sanitary authorities deliver to the consumers and which the public are compelled to take and to pay for. But the attempt was frustrated on the plea that any restrictions in this respect beyond those now existing ought to be embodied in a general Act and not in special Acts even though new powers were being asked for from Parliament. It remains to be seen whether the Government will bring in any such general Bill next session and what will be the attitude of those representing water companies to it if their own suggestion is thus complied with.

But little has as yet been achieved to diminish the prevalence and fatality of diphtheria, especially in large towns and cities, including the metropolis. Few who are conversant with the etiology of this disease now entertain any doubt that with the largely increased facilities for personal communication which are afforded to children at the age when they are most liable to be attacked by diphtheria which are the outcome of attendance in elementary schools there has been a marked increase in the amount of death from this disease. The majority of observers also feel confident that by reason of the aggregation of young children in schools diphtheria amongst them is apt at times to assume a character of special potency for spread. Some time since it was announced that the Education Department of the Privy Council intended to make inquiry into the subject, but no indication of any such investigation has as yet been apparent. It is therefore opportune that the London County Council should at the present moment be pressing the need for an exhaustive inquiry into the matter both upon the Local Government Board and upon the Education Department. Whatever can be done reasonably by school restrictions in this matter ought to be carried out without further delay.

The country has happily been free from any widespread epidemics whether it be considered as a whole or in regard of special communities and similarly we have not suffered from the importation of any foreign epidemics. Our relations with Bombay where plague has now so long prevailed have been fully maintained but only on three occasions have vessels that could be regarded as infected with that disease reached our ports. On each occasion the measures of precaution which have been adopted have sufficed to prevent any extension of the disease after the vessel had once come within the control of an English port authority. The last occurrence of this sort took place during the week ending Dec. 10th.

The most important event in relation to public health in this country which has taken place during the past year has been the passing of the Vaccination Act, 1898. This subject is treated at length on page 1790. No other legislation bearing upon public health calls for notice. Indeed, apart from the limited number of subjects to which we have adverted the year 1898 has been a somewhat uneventful one in so far as the public health is concerned.

The University of London.

After many years of waiting—and not of patient waiting—we have at last in our annual summary of events something definite and promising to chronicle concerning reform in the University of London. The Bill for appointing a Statutory Commission to deal with the questions arising out of the reconstitution of the University passed through the Committee stage of the House of Commons on July 26th of this year, was allowed a third reading on that date, and received the QUEEN'S assent on August 12th. The Commission immediately got to work, Mr. T. BAILEY SAUNDERS being appointed secretary. We tender our hearty congratulations to Sir JOHN GORST for the manner in which he piloted the Bill through

Digitized by Google

the Lower House, while we consider that the solution of the important problems in education which have been thus boldly tackled will redound greatly to the credit of the Government. That teaching functions should be added to the University of London is clearly for the benefit of the London medical student and this has been the main reason for giving prominence in our columns to all the schemes which have had this object in view. A *résumé* of these schemes, forming a history of the movement for reform in the University from its inception in 1864 down to its present interesting position, was published in our Students' Number of this year[1] and to this we refer our readers. A proposal to locate the University in the buildings of the Imperial Institute, in view of its insecure tenure of its present home, has received serious discussion and will necessarily call for criticism from some of those interested in University College, Gower-street.

The General Medical Council.

The General Medical Council has held three meetings in the past year. In addition to the ordinary meetings in May and November respectively a special meeting was held on April 5th and the succeeding day for the consideration of the Midwives Bill, then before Parliament, at the request of the Government. At that time the Council was without a President, in consequence of the lamented death of Sir RICHARD QUAIN. The meeting was summoned at the instance of the senior treasurer, Sir DYCE DUCKWORTH, who was voted into the chair. Thereafter Sir WILLIAM TURNER was duly elected President. His connexion with the Council on and off for twenty-five years, his active share in its work and knowledge of its procedure, together with his sound judgment and capacity for the transaction of business, account for the unanimity of his election. The first act of Sir WILLIAM TURNER after returning thanks for his election was to propose a resolution expressing sympathy with the family of the late President, which he did with much feeling. As the result of the two days' meeting the Council, basing itself mainly on the report of its Midwives Committee, came to a unanimous declaration, on the motion of Dr. DONALD MACALISTER, that the Bill submitted to the Council did not solve the question under consideration and it proceeded to lay down certain principles as being essential in any such measure. In one point the Council departed from the report of its committee on the suggestion of Sir WM. GAIRDNER. It reported in favour of licensing midwives annually instead of registering them, the licence to be granted by the local sanitary authority. A chief feature of the report of the Council was the emphasis with which it urged that any unlicensed woman, whether calling herself a midwife or not, who not being registered under the Medical Acts practised as a midwife for gain should be made liable to a substantial penalty. In the course of the Parliamentary session a deputation in favour of the Midwives Bill waited on the Lord President to urge the passage of the measure but he gave them no encouragement and advised them to seek an understanding with the General Medical Council. Accordingly they sought a conference with the Council, which was arranged. Sir RICHARD THORNE, Dr. GLOVER, Dr. MACALISTER, and Sir CHRISTOPHER NIXON were appointed a committee for this purpose. The conference was duly held. The deputation representing the Midwives Bill stated their objections to the system of licence and to the prohibition of practice as well as of titles by unregistered persons, but the committee representing the Council remained firm on these and other points. At the recent meeting of the Council the same committee, with the addition of Mr. HORSLEY, was appointed to watch any attempt at legislation on the subject in the coming session.

The second meeting of the Council extended from May 24th to the 31st. A novel subject for discussion arose early at this meeting on Mr. HORSLEY getting permission to call the attention of the Council to an alleged infringement of the rights and privileges of the members by the President in directing the Registrar to refuse a member the exercise of his right of inspection of documents, the property of the Council. The President explained to the complete satisfaction of the Council that in the course he took he acted entirely on the advice of the Council's counsel. The necessity of safeguarding these documents was universally admitted. A committee of inquiry into the conduct of legal business and the cost incurred was moved by Mr. HORSLEY and seconded by Dr. GLOVER, but the motion was lost. In the end a resolution was passed requiring members desiring access to the documents which are the property of the Council to obtain leave either from the Council, or the Executive Committee, or the President of the Council. In penal cases the leave of the Council itself must be given. It will be remembered that at the recent meeting the rule passed in May was found to be inconvenient and was referred to the Executive Committee for consideration and report at its next meeting.

At the May meeting an extraordinary case came under the judicial notice of the Council—that of a practitioner named JOSHUA HAMILTON HART—charged with associating himself with "Munyon's Homœopathic Home Remedies." Mr. HART stated that he had nothing to do with the medicines prescribed but only to say what the complaint of the patient was. The appropriate remedy followed of necessity on the complaint being labelled, being already fixed by the genius of MUNYON. The Council, of course, had no hesitation in removing the name from the Register. A very important improvement in penal procedure was made on the motion of Sir BATTY TUKE that no case of complaint should be considered by the Penal Cases Committee until a statutory declaration as to the facts of the case had been supplied by the complainant. In the educational part of the work of the Council in May one of the principal subjects dealt with was the consideration of a communication from the Secretary of State for the Colonies on Instruction in Tropical Medicine, Hygiene and Climatology. The Council did not see its way to lay any heavier burdens on the ordinary medical student, but strongly recommended that arrangements should be made by Government for special instruction of the sort for duly qualified practitioners selected for colonial medical service or intending to practise in the colonies. Another feature of the May meeting was the discussion of

[1] THE LANCET, Sept. 3rd, 1898, p. 591.

Digitized by Google

a series of recommendations, in the form of propositions, as to the course of study and examinations to be required of candidates for diplomas in dental surgery. There was great rejoicing over the completion of the new Pharmacopœia which was handed over to the Executive Committee for publication by the late President, Sir RICHARD QUAIN, on Feb. 19th—his last official act.

At both the May meeting and the November meeting communications on the subject of unqualified assistants occupied the time of a special committee presided over by Mr. TEALE without any change in the letter of the resolution adopted by the Council on Nov. 24th, 1897. At both meetings, too, reports were received from the Examination Committee on the reports of the inspector of the examinations of the Apothecaries' Hall of Ireland.

The lengthy proceedings of the November meeting are so recent and have been so fully commented upon in our columns that they need not detain us at the present time. The most important part of the work of the Council was its discussion of the report of the Education Committee on the list of preliminary examinations recognised by the Council and its deletion of the second-class certificate (first and second division) of the College of Preceptors. But clear warning has been given that further deletions will be made and that the notice of them will not be very prolonged. We must not forget to record the efficient action of the President in his communication with the Privy Council with regard to such an amendment of the Medical Act of 1858 as shall deprive any graduate or diplomate whose name has been erased under Section 29 of the right to use the title attaching to his degree or diploma so long as the erasure continues.

The British Medical Association.

The sixty-sixth annual meeting of the British Medical Association was opened at Edinburgh on Tuesday, July 26th, under the presidency of Sir THOMAS GRAINGER STEWART, M.D., LL.D., F.R.S. Edin., Professor of Medicine in the University of Edinburgh and Physician-in-Ordinary to Her Majesty the QUEEN in Scotland. That it was a success we need hardly venture to remind our readers, for not only is the capital of North Britain so associated with culture as to have earned for itself the *sobriquet* of Modern Athens but its architecture and surroundings possess all the attractiveness that visitors could desire. Added to this was the fact that everything that could be done was done for the convenience and comfort of members and their friends.

The Presidential Address dealt with a large number of questions affecting the relations and efficiency of the medical profession and may be described as a masterly performance. The Address in Medicine delivered by Professor T. R. FRASER was mainly occupied with a remarkably lucid and exhaustive account of the present position of science in regard to the share taken by toxins in the production of disease and the new aspect which has been given to the interpretation of the facts of infective disease and the prospects which are offered for their mitigation and abolition. The Address in Surgery was delivered by Mr. ANNANDALE who dealt with the present position of that branch of the healing art. In Psychological Medicine the name of Sir JOHN BATTY TUKE is an ample guarantee that the address was an able one. At the general meeting it was decided that medical defence should not be undertaken by the Association.

As a *rapprochement* between this country and the United States is so much in evidence just now it is noteworthy that among the social features of the Edinburgh meeting was a luncheon given by the Anglo-American Continental Medical Society whose object it is to serve as a bond of union between the British and American practitioners established on the continent of Europe and Northern America. At the annual dinner the toast of the evening was given by Professor BOWDITCH of Harvard College, Boston, U.S.A., who took occasion to remark on the essential unity of the two nations.

At the summer graduation ceremonial of the University of Edinburgh the honorary degree of LL.D. was conferred upon the following gentlemen among others: Dr. H. PICKERING BOWDITCH, Professor of Physiology in Harvard University; Sir WILLIAM BROADBENT, M.D., F.R.S; Dr. LAUDER BRUNTON, F.R.S.; Dr. EUGENE DOYEN of Paris; Dr. DAVID FERRIER, F.R.S.; Dr. JOSEPH FORSTER, Professor of Hygiene and Bacteriology in the University of Strassburg; Dr. CARL GERHARDT, Professor of Medicine in the University of Berlin; Mr. HUTCHINSON, F.R.S.; Dr. THEODOR KOCHER, Professor of Surgery in the University of Berne; Dr. AUGUST MARTIN, Professor of Gynæcology in the University of Berlin; Dr. JOHANN MICULICZ, Professor of Surgery in the University of Breslau; Dr. MORISANI, Professor of Midwifery in the University of Naples; Dr. William OSLER, F.R.S., Professor of Medicine in the Johns Hopkins University, Baltimore; Dr. WILLIAM S. PLAYFAIR; Dr. THOMAS RODDICK, Professor of Surgery in the M'Gill University of Montreal, ex-President of the British Medical Association; Dr. SIEGMUND ROSENSTEIN, Professor of Clinical Medicine in the University of Leyden; Dr. HERMAN SNELLEN, Professor of Ophthalmology in the University of Utrecht; and Sir RICHARD THORNE, F.R.S.

It was decided to hold the next meeting of the Association at Portsmouth.

The Metropolitan Hospital Sunday Fund and the Prince of Wales's Hospital Fund.

Under the Presidency of the Right Honourable Sir HORATIO D. DAVIES, K.C.M.G., M.P., Lord Mayor, the twenty-sixth year's collection of this Fund resulted in a total of £40,397 2*s.* 10*d.* The Rev. C. J. RIDGEWAY, M.A., of Christ Church, Lancaster-gate, headed the list of contributions with £1367; the Rev. Canon FLEMING, B.D., of St. Michael's, Chester-square, collected £1268; the Rev. J. STORRS, M.A., of St. Peter's, Eaton-square, £681; the Rev. Prebendary EARDLEY-WILMOT, M.A., of St. Jude's, South Kensington, £623; and the Rev. F. E. RIDGEWAY, D.D., of St. Peter's, Cranley-gardens, £501. Sir SAVILE CROSSLEY, Bart., again contributed £500, and a sum of £500 was also sent by him to "The Prince of Wales's Hospital Fund"; £300 were received from A. G. P.; "Delta" sent his twentieth donation of £200; and Mr. GEORGE HERRING gave £200. The sum collected this year may on the whole be considered satisfactory for it must be remembered that the exceptional influence of the special claims of the year of HER MAJESTY'S Diamond Jubilee has, probably, not yet ceased to be felt.

A recent report of the Prince of Wales's Hospital Fund

Digitized by Google

states that a sum of £30,000 is still required to meet the minimum necessities of the hospitals for the present year. Last year the Prince of Wales's Fund was the means of opening 180 beds which previously had remained closed for want of money. The amount in hand at the close of the financial year was £203,490, of which £32,500 were available for distribution.

Sanitation: Special Articles and Investigations.

The sanitary state of Belfast.—The articles published in the month of December, 1897, on the typhoid fever epidemic at Belfast were followed in February this year by a series (illustrated by some photographs) on jerry-building in that town. These showed the privy middens exposed to the public view from a frequented thoroughfare or, when situated in the privacy of a small backyard, placed so close to bedroom windows that there was no escape possible from the effluvia of the uncovered offensive matter. The household refuse and nightsoil which these open privies contained escaped into the yards or percolated through the walls into the dwelling-houses. In some cases the situation was aggravated by the presence of ponies, donkeys, pigs, or poultry in the small backyards. Here and there the cottages were of such a wretched description that the floor was not boarded. The inhabitants were so poor that they had no bedsteads but slept on a mattress placed on the bare, damp earth. Though quite exceptional still there were a few floorless houses in the very midst of the wealthy town of Belfast. The speculations in land and in jerry-building were explained and denounced, as was also the lack of energy on the part of the authorities in dealing with these matters. In contrast with the inefficient and antiquated methods of draining employed in Belfast we published some account of the new system of drainage now being installed at Bombay. Here the difficulty of low-lying levels is met by the employment of compressed air to raise the sewage at frequent intervals. Thus the sewers, even in the lowest districts, will have sufficient gradients to be self-cleansing.

The Ninth International Congress of Hygiene.—The fullest account of this important Congress, published at the time when it was held, appeared in our columns. From the general secretary, writing in the name of the Spanish authorities and organisers of the Congress, we have received courteous letters of acknowledgment for the large share of publicity which we gave to the efforts of the sanitary reformers of Spain. Though the Congress was held a few days before the outbreak of the war—i.e., from April 10th to the 17th—it was a great success. The hospitality and the courtesy of the Spanish people were displayed to the best advantage under the most trying circumstances. Even the American delegates to the Congress were treated with the greatest consideration and politeness. The debates, attended by some 2000 members and delegates, naturally embraced a great variety of subjects and several new and important questions were brought forward—such as, for instance, the treatment of infected walls in buildings or hospitals by inoculation in the same manner as living beings are rendered immune by antitoxins; the yearly school feasts when every child plants a tree so as to improve the climate; the cure of the bites of venomous snakes by inoculation of serum, &c. It is much to be regretted that the British delegation to this Congress was, comparatively speaking, small. The next Congress will be held at Paris in 1900, and it is to be hoped that on that occasion British sanitary reformers will be present in larger numbers and that British sanitation will figure to greater advantage.

Sanitation in Spain.—After the Congress our Special Commissioner was able to visit the military hospital at Cadiz and to depict its deplorable condition. On the other hand, he at great length described the new military hospital at Madrid which is a model for all nations. Then our Commissioner showed what great economies had been effected in the military medical services by the State. From the Central Laboratory at Madrid medical stores which had cost the Government 3,059,526 pesetas to produce had been sent out to Cuba since 1894. If these same articles had been bought on the spot they would have cost 8,826,248 pesetas and thus an economy of 5,766,722 pesetas was realised. (If there were no premium on gold the peseta would be equal to the franc or to 10*d.*) The various medical and hygienic educational institutions of Spain were likewise described as also were the medical services organised by the Spaniards in Cuba.

Morocco.—From Spain our Special Commissioner was able to pay a flying visit to Tangier, which by reason of its climate is so well suited for a health and winter resort. Since the last account which we published of Tangier in 1887 many improvements have been effected and a sort of European municipality has been brought into existence. These alterations, however, have the disadvantages of somewhat spoiling the appearance of the place which owes its charm to its purely Oriental character and to the great relief which it affords to the mind of the European traveller who on reaching Tangier experiences a complete change in all his usual surroundings.

Gibraltar and social purity.—From Tangier it is but a short sea passage to Gibraltar and we published an account of the sanitary progress recently accomplished in that important fortress. From 1851 to 1866 the average death-rate was 29·25 per 1000; from 1891 to 1895 it was 19·97; but last year it rose again to 23·56 per 1000, the zymotic death-rate being equal in that year to 3·77 per 1000. The chief sanitary defect is overcrowding, resulting to a great extent from the military exigencies of the situation. Gibraltar being also a very important commercial centre there is much to attract business men and workmen. Great efforts are being made to increase and improve the water-supply. The house drainage is good, the public sewers have been somewhat improved, but the method of ventilating the sewers is still very defective. At the military hospital there were evidences of unwise and exaggerated economy which would prove very costly if an emergency were to arise. The most startling fact published related, however, to the disastrous effect produced by the social purity campaign organised at Gibraltar. As nearly all the public women were foreigners it was the custom not to give them permission to reside in the colony unless they consented to be medically examined every week. As this examination did not differ from that to which they were accustomed before leaving their own country they readily assented and thus venereal

Digitized by Google

disease was kept somewhat in abeyance. But this did not suit the social purity agitators and some six or seven years ago this practice was abolished. The only measure which can now be taken is to send such women away altogether. To avoid this contingency several of them have preferred paying British subjects to marry them and then they cannot be sent away. The direct effect of the social purity agitation is that there is now a class of men in Gibraltar who are living on the prostitution of their wives. These women having by marriage become British subjects cannot, as was the case formerly, be compelled to reside in one particular and distant part of the town, but may frequent and corrupt any quarter of Gibraltar. All control having been abolished venereal disease is so prevalent that the inhabitants of Gibraltar lose no opportunity of going over to Spain where the women are safer. The consequence is that Gibraltar is looked upon as a sort of plague spot by the Spanish authorities. At Algeciras notably, where a great many English families from Gibraltar spend the hottest months of the summer, far more disease is prevalent among the Spanish women at that season, and as soon as the English begin to arrive the Spanish public women have to be examined with exceptional care to protect the population generally from British contamination. Finally, the women at Gibraltar are not at all satisfied with the abolition of control and do not thank the social purity party for what they have done. Far from considering a medical examination as a degradation they are voluntarily seeking to re-establish the control which the law used to enforce. They now pay medical men to examine them and are proud of the certificates which they thus obtain. It is becoming more and more the custom at Gibraltar to ask a woman for her medical certificate, and thus the very system which the social purity party have so strenuously denounced is being re-established by voluntary effort and by the women themselves.

Bordeaux.—Returning homewards from Spain our Special Commissioner examined closely the new sanitary service established at Bordeaux where a very ingenious system has been organised for compiling a complete sanitary record of all the dwellings of the town. Here also the practice of disinfecting by steam under pressure not only such bedding and clothing as are known to have been contaminated but also articles about which only doubts are entertained is gaining ground rapidly. The State pawn-shop causes all bedding which is pledged to be disinfected, and some of the more respectable auctioneers will not sell bedding which has not been first disinfected. The account of these new services in Bordeaux was followed by some description of the somewhat feeble and tentative attempts made in Paris to deal with the very difficult question of the spread of disease through laundries. In England the matter has been considered principally from the point of view of the danger which the public incurred of having the linen contaminated by the laundresses ; in France the fear is rather that the laundresses themselves may be contaminated by the linen. But, as the French would say, *l'un n'empêche pas l'autre.*

Diphtheria at Tunbridge Wells.—We sent a Commissioner to Tunbridge Wells where diphtheria had been exceptionally prevalent and he described a condition of things which for so prosperous a town should not exist. The fact is that it is almost impossible to obtain land for the building of workmen's cottages. Consequently the few cottages that exist are let at exorbitant rents and this occasions much overcrowding which, together with sewers that do not work satisfactorily, accounts in a measure for more sickness than there need be in so prosperous and well-situated a residential and pleasure town. At the recent elections of town councillors some medical men and others pledged to sanitary reform were at the head of the poll and the infusion of this new blood may bring about a better state of affairs.

The second typhoid fever epidemic at Belfast.—The recurrence in epidemic form of typhoid fever at Belfast, coming so soon after the epidemic of last year, induced us to institute a further inquiry into the condition of that town. The old grievances though so glaring and fatal in their consequence have not yet been removed. The privy closets still abound though it has been shown that typhoid fever occurred in 5·5 per cent. of the houses with privies and in only 2·7 per cent. of houses with water-closets. Nor has any measure been taken to deal with the contaminated subsoil. Whole districts are built on the rubbish, including the contents of the privies of the town, but how to prevent the evil results is so vast a question that no one seems to have the courage to approach it. Nor is anything said about the main drainage which as a scheme was devised for a smaller population and works in a very defective manner. That Belfast is absolutely unhealthy is proved by the exceptional number and fatality of cases of typhoid fever which occur among the police and others who are not natives of the town and well inured to its unwholesome characteristics. A new town council was, however, elected a year ago which contains a stronger element of progress.

The Royal College of Physicians of London.

Several matters of importance engaged the attention of the College at the various meetings of the Comitia. Some of these were of general interest whilst others related to medical education only. Steps were taken to promote the introduction of the University of London Commission Bill and the long preliminary struggle has at last terminated, although numerous difficulties will probably present themselves after the report of the Statutory Commission has been issued. The President, in conjunction with the President of the Royal College of Surgeons, addressed a memorial to the Secretary for War in behalf of reform of the Army Medical Department. This vexed question has also now been settled.

Whilst the debate on the Vaccination Bill was in progress the College forwarded to the Government a strongly worded resolution reiterating their conviction that vaccination properly performed and duly repeated is the only known preventive of small-pox.

The most animated discussion of the year took place on the subject of the preliminary education of the medical student. A report was submitted from the Committee of Management pointing out that although students were encouraged to complete their studies in chemistry, physics, practical chemistry, and biology before entrance on the professional course proper, and although certain institutions had been recognised as suitable places of instruction in these subjects, there was little gained

Digitized by Google

by the student, who was still required by the regulations to go through a course of five years at a medical school, no matter whether he had been registered previously or not. The committee therefore suggested that the regulation should be altered so that "the first of the five years of the curriculum may be spent in obtaining instruction in chemistry, physics, practical chemistry, and biology, either at a recognised institution or at a recognised medical school and that the candidate be required to spend four winter and four summer sessions from the date of passing Parts I. and III. of the joint examination at a recognised medical school and hospital before entrance to the examinations in medicine and surgery." After a prolonged discussion occupying the greater part of the time of two meetings of the Comitia this was carried.

The report of a special committee appointed on Oct. 28th, 1897, to consider the subject of elementary biology recommended that in order that the time devoted to the study of biology should not encroach on that given to anatomy and physiology the regulation for the second examination as to twelve months dissection be modified by words indicating that the period of dissection required by the regulations should be subsequent to the instruction required for the preliminary subjects—chemistry, physics, and biology.

A Special Leprosy Committee reported: "That the communicability of leprosy by direct or indirect means from lepers to the healthy must now be accepted as an established fact"; but further recommendations were referred to the Committee for certain alterations. The Committee on Infectious Puerperal Diseases recorded their opinion that with a view to the limitation of dangerous infectious diseases the London County Council would be acting rightly in adopting the view that the expression "'puerperal fever' should be taken to include septicæmia, pyæmia, septic peritonitis, septic metritis, and other acute septic inflammations in the pelvis occurring as the direct result of childbirth." Sir SAMUEL WILKS was re-elected President by a majority which showed the high appreciation of the College of his value in such a position. The Murchison Scholarship was gained by Mr. J. BASIL PAGE of St. Mary's Hospital.

The following were the lectures delivered during the year:—The Milroy Lectures, by Dr. S. MONCKTON COPEMAN, on the Natural History of Vaccination; the Goulstonian Lectures, by Dr. J. ROSE BRADFORD, on Observations on the Pathology of the Kidneys; the Lumleian Lectures, by Sir R. DOUGLAS POWELL, on the Principles which Govern Treatment in Diseases and Disorders of the Heart; and the Croonian Lectures, by Dr. SIDNEY MARTIN, on the Chemical Products of the Pathogenic Bacteria considered with Special Reference to Enteric Fever. Dr. W. M. ORD was the Bradshaw Lecturer, whilst the Harveian Orator of the year was Sir DYCE DUCKWORTH.

The Royal College of Surgeons of England.

A very uneventful year for the Royal College of Surgeons is drawing to its close. It can hardly be said that any substantial progress has been made towards the extension to the Members of the College of the right of voting at the election of the Council, but the general tone of the November meeting of the Fellows and Members was much better than that which has prevailed on previous occasions and we look forward with hope for better things in the not far distant future. The Council has at several of its meetings considered complaints of canvassing by Members of the College and has expressed its willingness to hear any evidence put before it, yet it has not been able to make a definite pronouncement in any individual case.

A few years ago half-yearly meetings were granted to the Fellows, but the proceedings have hardly ever been of much interest or importance and in January last no quorum could be formed. As a result of this the Council decided to do away with the January meeting, but unfortunately at the July meeting also a quorum was not present, only 26 Fellows attending. We fear that these meetings may cease to be held if the Fellows do not attend more regularly. In March the Council received a petition from some Fellows and Members which claimed that the right of appointment of the representative of the College on the General Medical Council legally belonged to the whole body of the Fellows and Members. There is much to be said in favour of the petitioners' view, but the Council was unable to admit the justice of the claim.

When prohibitive restrictions were threatened as to the practice of British medical men in Italy the Council succeeded in obtaining through the Secretary of State for Foreign Affairs an assurance that no such intention existed. In the matter, too, of the formation of the Royal Army Medical Corps the action of the President of the College was of great usefulness.

Sir WILLIAM MACCORMAC, Bart., K.C.V.O., was re-elected President in July, and at the election of members of Council Mr. JOHN LANGTON and Mr. HENRY MORRIS were re-elected and Mr. RICHARDSON CROSS was elected. Only 26 Fellows voted in person, but 651 voted through the post. Mr. PICKERING PICK and Mr. HOWARD MARSH were appointed Vice-Presidents.

Mr. PICKERING PICK delivered the Bradshaw Lecture in December, the subject being the Healing of Wounds. Sir WILLIAM MACCORMAC will be Hunterian Orator in 1899. Two former members of Council have died during the year—Mr. EDWARD LUND and Mr. HENRY LEE. The Jacksonian Prize was awarded to Mr. PERCY FURNIVALL, F.R.C.S. Eng., the subject being the Pathology, Diagnosis, and Treatment of the Various Neoplasms met with in the Stomach, Small Intestine, Cæcum, and Colon. The subject for the Jacksonian Prize in 1899 is the Pathology, Diagnosis, and Treatment of the Inflammatory Affections of the Nasal Fossæ and the Associated Sinuses and Air Cells. For the College Triennial Prize the subject is the Thyroid Gland, its Structure, Comparative Anatomy, and Physiology. Mr. CHARLES SISSMORE TOMES, F.R.S., and Mr. W. DUNNETT SPANTON were elected Fellows under the twenty years' rule. An academic gown has been chosen which Fellows of the College may wear on State occasions, and a similar privilege will probably be granted shortly to the Members.

The Council have applied in vain for exemption from corporation duty, but they have decided to appeal against the adverse judgment.

The Benevolent Agencies of the Profession.

The reports of the benevolent societies of the profession show not only that medical charities do not obtain the support which they deserve but that they do not receive the help which they need. Temporary or acute distress such as is dealt with by THE LANCET Relief Fund (the report of which will be published next week) is apparently not so great as during last year, or at any rate stationary, but the more chronic form of need is probably as prevalent as in the past. The forty-fifth annual report of the Royal Medical Benevolent College stated that the year with which it dealt had been one of great anxiety in consequence of large but necessary expenses; nevertheless, it is satisfactory to know that there was a small credit balance. The amount received from annual subscriptions was under £3500, while the expenses on the benevolent side of the institution are over £6000 annually. In an appeal which was issued in October last signed by Sir JOSEPH FAYRER, K.C.S.I., Dr. CONSTANTINE HOLMAN, and the Secretary, it was said:

"If each member of the profession would give 10*s.* or even 5*s.* a year for a very few years the position of the pensioners and foundation scholars would be placed on a secure financial basis and the Council would be able to improve the school and extend its usefulness still more."

The report of the committee of the British Medical Benevolent Fund for the year 1897 shows the amount received in subscriptions and donations to have been £1367. The sum paid out in grants was £1236. It is sad to note that many of the cases requiring relief had to be put off from month to month owing to want of funds. There are 107 annuitants of the fund who collectively receive £2168. At the last quarterly court of the Society for the Relief of Widows and Orphans of Medical Men applications for relief were read from 49 widows, 11 orphans, and 6 recipients from the Copeland Fund. £1197 11*s.* were recommended for distribution amongst them.

The Analytical and other Commissions of THE LANCET.

Towards the end of the year 1897 we instituted an inquiry into the quality of the milk supplied to the metropolitan hospitals. To that end samples were obtained under what we thought to be fair and representative conditions and brought to THE LANCET Laboratory for analysis. The result of the inquiry was interesting. Of the 11 samples obtained from the leading general hospitals in London 7 proved to be of good average quality, 2 of indifferent quality, 2 decidedly poor and in all probability watered, while 3 specimens contained distinct though not excessive quantities of boric acid. In the report of this Commission which appeared in THE LANCET of Jan. 1st, 1898, we commented upon the employment of preservatives in food for general purposes, pointing out that however justified this recourse may be in such cases the practice in the case of milk which is intended for the sick should be vigorously prohibited. We suggested that the officials appointed to take samples under the Food and Drugs Act should pay special attention to the hospitals whose supply of milk in many cases must be equal to the stock of the ordinary milk-shop. We have reason for believing that our inquiry bore excellent fruit, for we have since learned that some of the hospital authorities concerned have sought the assistance of the scientific departments connected with the institutions to examine and report from time to time on the quality of the milk supplied.

In THE LANCET of March 5th, 1898, we recorded some experiments made in THE LANCET Laboratory with certain hair combs which proved to be composed of a very highly and easily inflammable substance. The danger is increased by the fact that the hair fastener with which we experimented could only with difficulty be drawn from the hair. The ornament consisted in reality of two combs fastened together at one end by means of a hinge in the same way as a pair of compasses, the hair being caught up by the combs when interlocked. We found that a hot curling iron was sufficient in contact with this comb to start the evolution of dense fumes which are easily ignited even when some distance away from a flame. We mentioned an instance which was known to us of this accident having actually occurred. We urged that the public should be fully aware of the dangerous nature of these combs and we suggested that the manufacturers should be compelled to stamp plainly on all such articles the words "Highly Inflammable."

In the following issue of THE LANCET we pointed out the very common but mistaken notion that the electric incandescent lamp is free from heating effect. On the contrary we found in laboratory experiments that the heat of the electric incandescent lamp is considerable. When buried in cotton-wool, for example, the material soon scorches and ultimately bursts into flame, the lamp generally collapsing with a loud report. The bearing of this result upon the use of incandescent electric lamps in shop windows where a profusion of highly inflammable fabrics is displayed was pointed out as a corollary.

Much of the practical work in THE LANCET Laboratory this year has been devoted to an inquiry into the production, composition, and character of sherry. Sherry is a wine of some importance in medicine since it is the only wine ordered in the preparation of certain pharmaceutical compounds. Further, there has been considerable discussion in medical circles as to the effects of a wine containing sulphate of potassium which is the product of the so-called "plastering" process. We therefore thought the subject was one well worthy of investigation. Obviously this could not be thorough without an inquiry on the spot and an inspection from beginning to end of the processes which are concerned in the production of this wine, and accordingly one of our Commissioners visited the scene of sherry production, Jerez de la Frontera in Spain. We venture to think that the information so gained was of interest to our readers. A great number of analyses were subsequently made in THE LANCET Laboratory and the results together with the conclusions to which they pointed appeared in THE LANCET of Oct. 29th, 1898. It was shown that the "plastering" process was an exceedingly old custom which even PLINY mentions as ancient and that the process probably had its origin in the fact that the vintages were more satisfactory when the grapes had an unusual amount of the vineyard soil attached to them, the soil consisting largely of lime salts. The analyses which we made confirmed in a very interesting way the experience of the grower—namely, that without the treatment with sulphate of lime the wine develops but a feeble character. On the other hand, after

Digitized by Google

treatment with a small quantity of sulphate of lime which is dusted over the grapes a remarkable development of vinous ethers takes place. Our analyses offered an explanation of this from the fact that tartaric acid is largely set free by the sulphate of lime treatment, and this acting upon the alcohols produces the corresponding ethers. It was further shown that the adulteration of Spanish wines is exceedingly unlikely since grape juice in that country is the cheapest possible material for producing spirituous liquids.

A Select Committee of the House of Commons issued a report this year upon a subject with which a Commission of THE LANCET dealt practically in our columns on Jan. 4th, 1896, and the report of the Select Committee on Petroleum to which we refer was published in the second week of August. The upshot of this report was a recommendation of the adoption of a flash-point of 100° F.—that is, of about 27° above the flash-point of the oil commonly supplied. The Committee were careful to add, however, that in their opinion statutory powers should be created to enable the Secretary of State to issue orders affecting the manufacture and sale of lamps. In the report of THE LANCET Commission referred to we ventured to suggest that legislation could effectively deal with the danger arising from lamp accidents by insisting upon the sale of safely constructed lamps. We still doubt whether the Government will adopt the somewhat drastic measure recommended by this Committee—namely, to exclude for burning purposes all oil of a flash-point lower than 100°. We have pointed out also that the effect of this recommendation will be to necessitate in addition the use of specially constructed lamps. This will obviously and, as we think, unnecessarily complicate the future legislative requirements thus indicated.

Quite recently our analytical staff has been closely engaged upon the analysis of abortifacients—pills and potions—the results of which are contained in the three previous numbers of THE LANCET, the fourth article appearing in another place in our present issue. This analytical work has thrown no little light upon the unscrupulous and shameful methods which are described in the inquiry under the heading of "Quacks and Abortion: A Critical and Analytical Inquiry."

Under the heading of "Analytical Records from THE LANCET Laboratory" some 115 samples of foods and drugs have been reported upon during the year. This has involved the carrying out of 327 individual analytical determinations. If we add to these figures the analytical work concerned in the special work summarised above, the total number of samples examined reaches 140 and the number of analyses made amounts to no less than 452, which is distinctly in advance of the number recorded last year.

Hospital Abuse.

Our series of special articles on this subject was continued during the year, commencing with the town of Glasgow. Here the advance of sanitation has greatly reduced the death-rate and sick-rate, yet the facilities for obtaining medicine and advice gratuitously are ever increasing. From 1871 to 1880 there were beds provided by the hospitals which amounted to 2·7 beds per 1000 of the population. Since 1891 the proportion equals 4·2 beds per 1000 and if to this we add the fever hospitals and the workhouse infirmaries then the proportion is 9·5 per 1000. Of course this has led to much and manifest abuse and it is calculated that 52 per 1000 of the population received gratuitous medical treatment during the course of twelve months. The proportion of those treated at the public expense was 22·6 and of those treated by the charities 29·3 per 1000 of the population.

From Glasgow our Special Commissioner proceeded to Bradford and there, also, the death-rate has considerably decreased, falling from 21·01 in 1882 to 16·77 per 1000 in 1896. Nevertheless, the number of persons who attend the hospitals and obtain gratuitous medical advice has greatly increased. The evidence collected all went to show that a better class of people now avail themselves of these facilities and an incident was related where one of the members of a hospital staff was invited to a Christmas dinner given in the handsome villa of one of his hospital patients. Then there is also a plethora of trivial cases such as boils, &c. Where there is a medical school it is necessary that the students should see such cases, but as there is no medical school at Bradford persons suffering from such slight ailments ought not to crowd the out-patient department and thus waste the time of the medical staff.

Brighton, again, is a town with a low death-rate and, what is more, a town where there is comparatively little poverty and many wealthy inhabitants. Nevertheless, out of 3704 births registered in 1894, no less than 1240 were attended by one charity. In the same year 38,113 hospital tickets were distributed amid a population of 115,000. The grievances and abuse arising from this state of things were described at length by our Special Commissioner and he related the efforts made by the local practitioners to cope with this difficulty.

Noteworthy energy has been shown by the medical men practising in the Eastern suburbs of London. Here a "Medical Protection Society" was recently formed, and the successful action already taken by this active body supplied the subject-matter of several special articles and reports. These appeared under the title of "The Abuse of Nursing Institutions," for it was against the Plaistow Maternity Charity that the energies of this body were first directed. This is another form of hospital abuse and, as interfering with the midwifery fees which medical practitioners are legitimately entitled to receive, is a very important matter. But the East Suburban Medical Protection Society have dealt with many other questions. They have drawn up a black list of patients who do not pay, they have established a system for collecting debts, they attempt to check unprofessional conduct, and they have insisted on the adequate representation of the medical profession on the boards of management of hospitals, &c. In a word they are engaged in organising medical men for the defence of their economical interests and the honour and dignity of their calling.

The Battle of the Clubs.

Though from time to time we have published reports reaching us from various districts concerning the struggle between the medical practitioners and the medical aid associations we have only made one special investigation on

Digitized by Google

this subject during the year. This was at Tunbridge Wells, a town from which we had received several complaints. Here, however, the grievance was not so acute as it was found to be in other towns, but the fact that the medical officer of the Friendly Societies' Medical Association did not receive more than 2½*d.* per visit or consultation shows that it was bad enough. Unfortunately there is no medical union in this town, though some of the local medical practitioners have individually acted with great spirit and energy. Still, these isolated efforts are very risky and uncertain in their result and it is time that the medical practitioners of Tunbridge Wells should seek to unite for common action.

Honours to Medical Men.

It now becomes our pleasing duty to record the honours which have been bestowed upon members of the profession during the past twelve months. In the list of those receiving New Year honours the names of six medical men appeared and it was noticeable that four out of the six were associated with Scot h degrees. This was as it should have been, for while last New Year's list was essentially English the Jubilee list was an Irish one. The New Year's list for 1898 contained the names of JOHN STRUTHERS, M.D., F.R.C.S. Edin., LL.D. Glasg., and JOHN BATTY TUKE, M.D., F.R.C.P., F.R.S. Edin., upon whom were conferred knighthoods; of WILLIAM TENNANT GAIRDNER, LL.D., M.D., F.R.C.P. Edin., F.R.S., Physician-in-Ordinary to Her Majesty the Queen in Scotland, who was created a Knight Commander of the Bath; of Brigade-Surgeon-Lieutenant-Colonel GEORGE KING, C.I.E., who was raised to a Knight Commandership of his Order; and of Surgeon-Lieutenant-Colonel SAMUEL JOHN THOMSON and Surgeon-Major FREDERICK FITZGERALD MACCARTIE, who were appointed Companions of the Most Eminent Order of the Indian Empire. On Her Majesty's birthday honours were received by Surgeon-Lieutenant-Colonel J. G. ROGERS, D.S.O., head of the Egyptian Sanitary Department, who was made a K.C.M.G., and Dr. ANDREW MILROY FLEMING, Principal Medical Officer of the British South African Police, who was made a C.M.G. Surgeon-Major-General ROBERT HARVEY, D.S.O., was made a C.B., and Brigade-Surgeon-Lieutenant-Colonel A. M. BRANFOOT, Professor of Midwifery in the Madras Medical College, a C.I.E.

Mashonaland and North-west Frontier rewards were announced on the same occasion and were as follows, as far as decorative Orders are concerned: To be Knight Commander of the Most Honourable Order of the Bath: Surgeon-Colonel GEORGE THOMSON, C.B., Indian Medical Service. To be Companions of the said Most Honourable Order: Surgeon-Colonel EDMOND TOWNSEND, Army Medical Staff, and Surgeon-Colonel GEORGE MCBRIDE DAVIS, D.S.O., Indian Medical Service. To be Companions of the Distinguished Service Order: Brigade-Surgeon-Lieutenant-Colonel CHARLES HENRY SWAYNE, Army Medical Staff; Surgeon-Major JOHNSTON SHEARER, Indian Medical Service; Surgeon-Captain THOMAS HERBERT JOHN CHAPMAN GOODWIN, Army Medical Staff; Surgeon-Captain JOHN FISHER, Indian Medical Service; Surgeon-Captain WILLIAM SELBY, Indian Medical Service; and Surgeon-Lieutenant JAMES HENRY HUGO, Indian Medical Service.

Among the Soudan Gazette honours occur the names of Surgeon-General WILLIAM TAYLOR, and Colonel W. H. MACNAMARA, R.A.M.C., who received the Companionship of the Order of the Bath; and of Lieutenant-Colonel G. A. HUGHES, R.A.M.C., Major E. M. WILSON, R.A.M.C., Major H. B. MATHIAS, R.A.M.C., and Captain C. S. SPONG, R.A.M.C., who received the Distinguished Service Order.

During the year Mr. PEARSON ROBERT CRESSWELL, F.R.C.S. Edin., Lieutenant-Colonel Commandant of the 3rd V.B. Welsh Regiment, was made a Companion of the Bath.

Of the Order of the Hospital of St. John of Jerusalem in England Sir RICHARD DOUGLAS POWELL, Bart., M.D. Lond., Mr. WILLIAM HAMERTON JALLAND, F.R.C.S. Eng., and Surgeon-Major-General WILLIAM ROE HOOPER, C.S.I., were made Knights of Grace.

The Roll of the Royal Victorian Order has been augmented during the year by the names of Sir WILLIAM MACCORMAC, Bart., Sir FRANCIS LAKING, Mr. A. D. FRIPP, and Fleet-Surgeon A. G. DELMEGE, M.D. R.U.I. The two former gentlemen have been appointed Knights Commanders of the Order and the two latter gentlemen Members of the Fourth Class, in recognition of their services in connexion with the accident met with by His Royal Highness the PRINCE of WALES. Staff-Surgeon JAMES LAWRENCE SMITH who attended the late Prince HENRY of BATTENBERG on the *Blonde* was appointed a Member of the Fourth Class of the same order.

Captain CHARLES CHRISTIE FLEMING, R.A.M.C., employed with the Egyptian Army, was made a Companion of the Distinguished Service Order in recognition of his services during the recent operations in the Soudan.

Among the foreign Orders which have been bestowed upon members of the profession during the year the first place must be given to that of the Cross of the Legion of Honour which was conferred upon Dr. BARTEL, a young naval surgeon employed on active service in Upper Dahomey. During the affairs of Nov. 4th and 8th, 1897, while serving with the Borgou column, this officer carried out his difficult duties to the wounded under a perfect rain of arrows. Dr. KESER, Physician to the French Hospital and Dispensary, was made a Knight of the Legion of Honour. Sir WILLIAM H. FLOWER, K.C.B., F.R.C.S. Eng., F.R.S., Director of the Natural History Department of the British Museum, and President of the Zoological Society of London, was the recipient from the German Emperor of the Royal Prussian Order *Pour le Mérite* for Science and Art; and the QUEEN REGENT of SPAIN created Mr. CHARLES LANE SANSOM, F.R.C.S. Edin., a Knight of the Order of Isabella.

Our list is fittingly concluded by the record of the latest addition to the names of medical heroes who have gained the Victoria Cross—i.e., that of Surgeon WILLIAM JOB MAILLARD, M.D. Lond., of the Royal Navy. The decoration was conferred for conspicuous bravery during the outbreak at Candia. On Sept. 6th, 1898, during the landing of seamen from Her Majesty's ship *Hazard* Surgeon MAILLARD, who had disembarked and reached a place of safety, returned through a perfect deluge of bullets to the boat and endeavoured to

Digitized by Google

bring into safety ARTHUR STROUD, ordinary seaman, who had fallen back wounded into the boat as the other men jumped ashore. Surgeon MAILLARD failed to bring STROUD in only through the boat being adrift and it being beyond his strength to lift the man (who was almost dead) from so unstable a platform. Surgeon MAILLARD returned to his post with his clothes riddled with bullets though he himself was happily unhurt. It is worthy of record that this officer is the only medical man in the Royal Navy holding this much coveted decoration.

Obituary.

In glancing over our Obituary columns for the year we find ample illustration of the many-sidedness of our profession and many proofs of the fact that some even of our busiest practitioners find time to do much public work. There are numerous examples of longevity, though there are too many cases in which the strain and pressure of life brought it prematurely and abruptly to a close. Mr. HENRY HAYMAN, F.R.C.S. Eng., of Stokenchurch, Oxfordshire, a man of high culture, attained the age of eighty-six years but not without a breakdown in his health in mid-age fifty years ago; after a rest he recovered and achieved the age mentioned. Mr. JOHN BARRITT MELSON, M.D. Cantab., a good classical scholar, a preacher among the Wesleyans, a friend of FARADAY, who, as Professor of Natural and Experimental Philosophy in Queen's College, Birmingham, had for pupils the late Archbishop BENSON and the present Bishop of DURHAM, died at the age of eighty-seven years. Mr. JOSEPH JOHN FOX, M.R.C.S. Eng., L.S.A., of Stoke Newington, who found his recreation from the fatigues of practice in the study of the calculus of variations and the dynamics of a particle and who sent five of his six sons into the medical profession, died at seventy-nine years of age. Mr. KESTER EDWARD KNIGHT, M.R.C.S. Eng., L.S.A., died at Southsea at the age of eighty-four years, having been 60 years in practice. Mr. JOHN STEWART, R.N., M.D. St. And., of Perth, a staunch advocate of total abstinence, died at eighty-nine years of age. He had served in the *Bellerophon*, was at the siege of Sebastopol, and had seen much service. Mr. THOMAS GIORDANI WRIGHT, M.D. Leyden, was born in Wakefield and practised there for sixty-six years, reaching the age of ninety years. Mr. ROBERT WALLIS, M.R.C.S. Eng., L.S.A., of Old Ridley, Northumberland, a pupil of LISTER, was an instance of a successful practitioner retiring and successfully assuming all sorts of public functions as Justice of the Peace and District Councillor and remaining active up to the age of eighty-eight years. So was Mr. MAURICE DAVIS, M.D. St. And., who on the loss of his wife retired from a most successful practice and found his solace in the active discharge of magisterial and other duties. Mr. HENRY ALFORD, F.R.C.S. Eng., qualified in 1828 and retained good health up to within a fortnight of his death at ninety-two years of age. Mr. AUGUSTIN PRICHARD, M.D. Berlin, F.R.C.S. Eng., of Bristol, son of the famous ethnologist and an ophthalmic surgeon, died at eighty years of age. Mr. JOHN STEELE PERKINS, F.R.C.S. Eng., of Exeter, died at ninety-one years of age. Mr. GEORGE ROPER, M.D. Aberd., died at seventy-five years after every variety of practice and experience and much travel, through all of which he bore himself well and in a way that called forth a very graphic tribute in our columns from the President of the Royal College of Physicians of London, Sir SAMUEL WILKS. Mr. WILLIAM FREDERICK CLEVELAND, M.D. St. And., of Maida Vale, was at the time of his death President of the St. Andrews Medical Graduates' Association. He was a very much respected practitioner and had filled many offices of honour in the profession. Unfortunately we have had to record many deaths all too premature. Mr. HUGH CALDERWOOD, B.Sc., M.B., C.M. Glasg., of most brilliant promise; DUNCAN JAMES CADDY, M.D. Durh., of Her Majesty's Colonial Service; and Mr. WILLIAM FRANCIS ADAMS, L.R.C.P. Lond., M.R.C.S. Eng., senior assistant medical officer of the Cornwall County Asylum, all died young—the last, only twenty-six years of age, dying in his bed in syncope from fatty degeneration of the heart. Mr. THOMAS W. MUIR LONGMORE, M.R.C.S. Eng., L.R.C.P. Lond., son of the late Sir THOMAS LONGMORE, died at Luxor at the age of thirty-four years. One of the saddest deaths in the year was that of Mr. JOHN ANDREW MALCOLMSON, M.D. R.U.I., the gifted medical officer of health of Middlesbrough, who at the age of forty-six years died at his post, so to speak—that is to say, from pressure of work in the great outbreak of small-pox, bravely fighting the epidemic. Mr. LEONARD REMFRY, M.D. Cantab., died at the age of thirty-eight years. The death of Mr. HENRY CASE, M.R.C.S. Eng., L.S.A., at the early age of forty-five years, whose work in the Leavesden Asylum and elsewhere had been so good, was a misfortune for the insane. So was the death of Mr. HACON, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., of Christchurch, New Zealand, who was medical officer of an asylum but who found time to distribute through the colony a large quantity of lymph obtained from calves inoculated by himself.

Some very distinguished members of the profession have passed away in the course of the year. In an early number of THE LANCET we had to record the death of Dr. GREGORY ANTONOVITCH ZAKHARIN of Moscow who enjoyed the favour and confidence of the late Tsar and who had the largest and most lucrative practice in Russia. Though Dr. ZAKHARIN did not escape the fierce criticism which is apt to gather round the work of Court physicians when it fails to achieve impossibilities, he will be long remembered for his rare powers of diagnosis and his valuable clinical lectures. M. JULES PÉAN died from influenza at the age of sixty-seven years. He was a very remarkable man. The son of a miller and often supporting himself as a student by coaching his fellow students, he attained the very highest eminence as a surgeon, especially in abdominal surgery. He laughed at criticism. He is said, probably with exaggeration, to have made £40,000 a year. Dr. JAMES MURPHY'S graphic notice of him in our obituary columns is worthy of being re-read. In August we had to record the death of Professor WILLIAM PEPPER, M.D., Provost of the University of Pennsylvania, Professor of the Theory and Practice of Medicine, and editor of a System of Practice of Medicine by American Authors. The cause of Higher Medical Education in the States and all good causes have lost by his death a valued friend. About the same time we had to report the death of an equal friend of medical education and reform in

Digitized by Google

India, KAIKHOSRO NASARVANJI BAHADHURJI, M.D. Lond. The event evoked a great expression of respect from the native members of the profession. The medical world of London has lost in the course of the year some of its most active and conspicuous members—amongst others Sir RICHARD QUAIN, Bart., M.D., F.R.C.P. Lond., F.R.S., &c., President of the General Medical Council, and Mr. ERNEST HART, M.R.C.S. Eng., D.C.L. Durh. (*hon. causâ*). Sir RICHARD QUAIN'S age at death was eighty-two years. His long and intimate connexion with the Royal College of Physicians of London, the London University, and the General Medical Council, his valuable services to these bodies, and his position in society and in the profession are matters of history. His pathological work and his great "Dictionary of Medicine" together with the force of his personal qualities will secure his not being forgotten for many years. Mr. ERNEST HART was not known much in connexion with practice but as the editor of the *British Medical Journal* and one who in many ways brought the influence of the profession to bear on public questions he will be remembered. In our first number of the year we recorded the death, at the age of seventy-five years, of WILLIAM WADHAM, M.D. St. And., F.R.C.P. Lond., &c., who will be long and well remembered as Dean of St. George's Hospital Medical School and a good type of the physician and teacher of his day. Mr. CHARLES WEST, M.D. Berlin, F.R.C.P. Lond., so well known for his works on Diseases of Women and Children and as a chief promoter of the Great Ormond-street Hospital for Children, died at the age of eighty-two years. We have lately had to record the death of a very distinguished member of HER MAJESTY'S service and of the medical profession—that of WILLIAM CAMPBELL MCLEAN, C.B., LL.D., M.D. Edin., Surgeon-General, Indian Medical Service, Honorary Surgeon to the Queen. He was of Highland descent and was born in 1811. He went first to India in 1833. He served in China in 1840 but in 1843 he returned to India. When he came back to England in 1855 he had been absent on continuous service for seventeen years. He was appointed the first superintendent of the first Vernacular School in India, the students being all Mahomedans. On the foundation of the Army Medical School at Netley he was appointed to teach tropical diseases and it is estimated that 1476 medical officers received instruction from him. The mere enumeration of such services is an education to those who stay at home at ease. Of the same kind and significance was the life of Surgeon-General ALEXANDER SMITH, C.B., M.D., L.R.C.S. Edin., who died at the age of seventy-four years, suddenly, after long and distinguished service in the Crimea, at Sebastopol and at the Redan, and against the Afridis and other tribes in the Afghan war of 1878. Fleet-Surgeon CHARLES ALBERT MACAULAY, M.D. R.U.I., died at Wei-hai-wei. He was a man of distinguished merit and had been present at the bombardment of Alexandria and at Tel-el-Kebir. Amongst home practitioners whose deaths have been much regretted we must not forget that of Mr. EDMUND LUND, F.R.C.S. Eng., of Manchester at the age of seventy-five years, or that of Mr. JOHN HODGSON WRIGHT, M.R.C.S. Eng., of Halifax, from neurotic angina following influenza. Mr. WRIGHT was a very charitable man, his favourite charity being that of providing nurses for the poor and a home for twelve incurable patients.

In the closing weeks of the year we have had to record the life and death of two members of the profession of the very highest merit—of Sir WILLIAM JENNER, Bart., M.D., F.R.C.P. Lond., F.R.S., and ALFREDO ANTUNES KANTHACK, M.D., F.R.C.P. Lond., F.R.C.S. Eng., Professor of Pathology in the University of Cambridge. The death of CHARLES JOHN HARE, M.D. Cantab., F.R.C.P. Lond., and that of WILLIAM MUNK, M.D., F.R.C.P. Lond., Harveian Librarian of the Royal College of Physicians of London, occurred at ripe ages, but leave a great blank in the College of Physicians and in the profession.

There are many other names in our own Obituary columns which deserve to be recalled here; but we must forbear. We shall make one exception in favour of a lady practitioner, MABEL ELIZABETH WEBB, M.B. Lond., who won golden opinions from all who knew her and worked with her as the curator of the museum at the Royal Free Hospital. For fourteen years she had laboured under symptoms of gastric ulcer, temporarily cured, it seemed, by a holiday in Egypt, only to return under the hospital conditions of her life at home.

Such are specimens of the men and women moulded in the profession of medicine. Many of them, it seems to us more than the average, were called to their account suddenly. But to true servants working "ever as in the Great Taskmaster's eye" that does not matter. By a plentiful use of their talents in all the great spheres of life—in the army, in the fleet, in private practice—they have sustained the honours of the profession and earned the "well done" of the Master whom most of them served in true piety and humility.

Annotations.

"Ne quid nimis."

A GIFT TO SCIENCE AND HUMANITY.

THE announcement which appeared in the morning journals of Dec. 23rd that Lord Iveagh had offered half a million to be devoted to two great objects of public importance may be said to have excited a thrill of admiration throughout the country. It was not the magnitude of the gift alone that evoked this feeling, although in point of munificence it has been seldom excelled. It was rather the spirit which animated the donor and the objects which he had selected as most worthy to be furthered by his wealth which fastened on the imagination and the sympathy of the people. Take first his benefaction of £250,000 to his own city. For long has Dublin striven to improve the sordid conditions under which so large a proportion of her inhabitants dwell and much credit is due to the municipal and sanitary authorities for what has already been effected towards the improvement of those conditions with the gratifying result of a diminishing sickness and death-rate. But very much remains to be done; many slums and rookeries need to be swept away and more healthful dwellings to be erected before the metropolis of Ireland can boast of her beauty or her health. Now comes this munificent offer of Lord Iveagh, a representative of a family to whom already Dublin owes much in the matter of public

Digitized by Google

improvements, and with the aid of this gift a whole insanitary area will be replaced by dwellings fit for the habitation and the health of the artisan class. There is a poetic justice as well as a spirit of generosity in this rendering of their wealth by Lord Ardilaun and Lord Iveagh to the city with which their interests are bound up and their fortunes knit. Dublin may well be proud of having such worthy sons who thus prove to the world that they are not unmindful of the claims of citizenship. Had Lord Iveagh limited his bounty to this great local scheme his name would have still been highly honoured, but how much greater is the recognition of his generous deed when simultaneously it is announced that he has also devoted a like sum to another and wider purpose. With one hand he assists the practical operations of the sanitary reformer just where this aid is most needed; with the other he endows science with the means for prosecuting researches upon diseases that flourish under the conditions against which the sanitarian strives. Surely this is the true spirit of philanthropy combined with practical wisdom and foresight which makes it all the more worthy of public approbation. The Jenner (formerly known as the "British") Institute of Preventive Medicine, founded by Lord Lister and other distinguished men, has, like all scientific undertakings in this country, had to exist upon private contributions. Crippled by lack of material resources it has only quite lately entered into possession of appropriate buildings and its association with the name of Jenner would, it was hoped, lead to a more widespread recognition of its objects besides claiming support from those who regard the work of the founder of vaccination as beneficent in itself and as the precursor to the scientific researches upon the origin, nature, and prophylaxis of infective disease which originated with Pasteur and which now embrace so wide a field. By Lord Iveagh's generosity the Council of the Institute—or rather the trustees who will be appointed by that Council, the donor, and the Royal Society—will have at their command resources ample enough to establish the Institute on a permanent basis and to expand its useful work. The Institute will emerge from its comparative obscurity and will become a centre of scientific activity equal to any of the State-established laboratories of foreign countries, but founded and maintained by private enterprise. The letter addressed to the press by Lord Lister, the chairman of the Council, and Professor Roscoe, the treasurer, in which the munificent gift was announced stated in general terms the conditions under which it was offered and accepted. Here, too, as with regard to his Dublin benefaction, Lord Iveagh has marked his liberality in giving by an equal liberality in acting. There is no narrow restriction imposed on the trustees as to the manner in which they are to dispose of this rich endowment. The extension of buildings, the adequate remuneration of the staff, the prosecution of scientific inquiries into disease at home and abroad, the foundation of fellowships and scholarships to encourage the prosecution of these studies, and the provision for the maintenance of the establishment—these are conditions which can be interpreted in the freest spirit and which we may be sure will be faithfully carried out. In recognising the great value to medical science of this memorable gift we cannot do better than quote from the letter referred to, the expressions in which will be endorsed by all who value the labours of science. Lord Lister and Professor Roscoe say: "Lord Iveagh, in our opinion, deserves the gratitude of the nation for thus munificently providing for the cultivation in the British dominions of biology and the allied sciences for the good of mankind in an institution which thenceforth will compare favourably with any similar establishment in other parts of the world." We may rejoice, too, at the evidence which this noble gift shows of the estimation in which the life-saving labours of those who pursue science in the spirit of Jenner or of Pasteur or of Lister are coming to be regarded by the world at large. When we consider how much has been done by men of science to enlarge our knowledge of diseases, how often that work has entailed sacrifice of self, and how poorly requited it often has been we may well take heart at the awakening of public sympathy in those labours. Professor Virchow on his return from his visit to England last October has reprinted the address which he delivered in London at the International Medical Congress in 1881 and has appended some remarks which show that he has been struck by the signs of this appreciation here. He especially dwells upon the admirable laboratories at Liverpool at the opening of which he assisted and expresses his gratification at the fact that they were established by the munificence of a private individual—the Rev. S. A. Thompson-Yates, whilst the occasion of their inauguration was celebrated by the leading citizens. May we not regard, then, with some justifiable pride this fact of the practical encouragement of scientific research by our wealthy compatriots and trust that the benefactions of Lord Iveagh and Mr. Thompson-Yates will be followed by others devoted to the like objects of the common weal?

SIX DAYS' BICYCLE RACE IN NEW YORK CITY.

ANOTHER exhibition of human beings bringing themselves to the level of animals for the sake of incommensurate gain and of unenviable fame has just taken place in New York City. We say incommensurate gain because no sane person would contend that even the sum of money received by the leaders can compensate them for the harm which such extraordinary exertion, coupled with the fearful strain put upon the nervous system by the want of sleep, must do them both in body and mind. The fame, too, resulting to the participants in a contest of this description is unenviable, because every sensible person has the feeling that it is pitiable rather than praiseworthy for a man thus to prostitute his physical powers. If any good end were reached the case would be different, but we are already well aware that man can easily outvie in staying endurance any other animal. One race of this kind is quite enough. Emulation is all very well, but when it is carried to the lengths recently witnessed in New York it is neither more nor less than inhuman. The reports given in the "yellow journals" of the latter stages of the six days' contest were simply revolting and enough to occasion doubt as to whether instead of living at the end of the nineteenth century we had not slipped back to 200 B.C. But when all is said and done the blame of such exhibitions being possible rests on the heads of those who are willing to pay to witness men in all cases injuring themselves and in some instances probably shortening their lives by many years. The *New York Herald* in a leading article in its issue of Saturday, Dec. 10th, expresses the sentiments of the majority of the rational members of the community in the following words: "The bicycle race which is being so hotly contested by the leading competitors will soon be ended and the foolishly coveted prize of championship will be awarded accordingly. The lesser lights will take their respective places in the line of relative merit and the question of brute force and misapplied pluck as against reason and moderation will be answered for a time at least. To such as have read from day to day of the sufferings of the riders and the overstrain of their physical energies it must be plain enough that the victory, great as it may appear to the parties most directly interested, will be dearly bought. ..... Stimulated by music, goaded by cheers, and sickened by the foul emanations of an ever-present crowd, the pitiable victims of the showman, gatekeeper, and trainer receive no more consideration than the racehorse with spur in side or whip to neck or the gladiators of old who trusted to the

Digitized by Google

mercy of the down-turned thumb when nothing more was left. Can we wonder that the riders fall from their wheels from sheer weakness, gulp their food as they go, wobble along in dazed unconsciousness, and cry for the sleep they dare not take. While the race shows in a great degree what persistent training can accomplish in keeping the men on the track until the finish in spite of crippled limbs, stiffened muscles, aching stomachs, and inflamed eyes, the ultimate damage to the health of all the participants must sooner or later be manifest either in premature stalling of energy or the insidious collapse of progressive invalidism. At the best what will the results of the race demonstrate? Nothing more than the fact that man, the noblest work of God, with a physical organism unequalled in its adaptability to everything high and glorious, is willing to pedal round a boarded ring for days and nights merely to prove that he can outog a dog on the treadmill or tire a horse on his own track. The absurd interest manifested in the outcome of the struggle proves the necessity of educating the public to a higher appreciation of what is real sport and healthy athletics. It is against the gross abuse of the thing as done at the Garden that every sensible person has a just right to complain. ..... After the last bicycle tournament many of the participants were compelled to keep their beds for weeks in order to recover even partially from the effects of the wilful and persistent overstrain of their strength. It is by no means unlikely that a similar experience awaits some of those who are now being praised for their staying powers, long stretches, and desperate spurts." As will be observed the foregoing remarks were made before the conclusion of the race. It may be mentioned that the winner succeeded in breaking the record, that he covered more than 2000 miles in the six days, that several of the other competitors had to be taken off the course in an exhausted and broken-down condition, and that the organisers of the contest are stated to have netted more than £6000 clear profit.

THE VACCINATION RETURNS OF THE LOCAL GOVERNMENT BOARD.

THE vaccination returns published in the supplement to the annual report of the Local Government Board refer to the year 1895. There is no doubt that this unavoidable delay robs them in some measure of their interest, especially under present circumstances. Yet they contain much useful and suggestive information. The proportion of births "not finally accounted for" and conveniently looked on as representing default, amounted to 20·5 per cent. of the whole. In the metropolis the figure was 24·9 per cent. and in the provinces 19·8 per cent. The way in which default has varied since the Act of 1871 came into operation is shown in the following table of percentages:—

—	Metropolis.	Rest of England.	—	Metropolis.	Rest of England.
1872	8·8	4·5	1884	6·8	5·3
1873	8·7	4·2	1885	7·0	5·5
1874	8·8	4·1	1886	7·8	6·1
1875	9·3	3·8	1887	9·0	6·7
1876	6·5	4·0	1888	10·3	8·2
1877	7·1	4·1	1889	11·6	9·6
1878	7·1	4·3	1890	12·0	10·9
1879	7·8	4·5	1891	16·4	12·9
1880	7·0	4·5	1892	18·4	14·3
1881	5·7	4·3	1893	18·2	15·7
1882	6·6	4·5	1894	20·6	19·0
1883	6·5	4·9	1895	24·9	19·8

Unsatisfactory as these figures are it is certain that if they could be brought up to date they would be much more so, something like 30 per cent. being now the estimated amount of default. The default is, of course, most unequally distributed. Taking the counties, the Leicestershire deficiency is no less than 76·5 per cent., and Bedfordshire with 75·4 per cent. comes very close at its heels. Northampton takes third place with 63 per cent., and then there is a big drop to 40 per cent. in the small county of Radnor (the only Welsh county which shows very badly), and 35 per cent. in Derbyshire. The best figures are found in Anglesey (3·0 per cent.) and Westmoreland (3·4 per cent.), and these were in 1895 the only two counties which had a percentage lower than that of the provinces as a whole in the best year, 1875, when the default was only 3·8 per cent. In the metropolis the years of low-water mark were 1881 with 5·7 per cent. and 1876 and 1883 with 6·5 per cent. The educative influence of a small-pox epidemic has no doubt much to do with the figures for 1881 in London. In 1895 the worst unions in London were Bethnal-green, 73·0 per cent.; Hackney, 63·4; Mile End Old Town, 63·1; and Shoreditch, 47·5. The best were Woolwich, 4·7; Whitechapel (which has now, alas, gone far astray), 5·3; and George-street Hanover-square, 5·8. In the provinces Barrow-on-Soar in Leicestershire (87·3 per cent.) and Leighton Buzzard in Bedfordshire (86·3 per cent.) share a bad pre-eminence. No less than fourteen unions show a default of over 80 per cent., 18 of between 70 and 80 per cent., 13 of between 60 and 70 per cent., and 14 of between 50 and 60 per cent. In only 69 unions is the default less than 5 per cent., and in 174 it is between 5 and 10 per cent. It is for the public welfare that the facts with regard to popular watering-places and health resorts should be known and it is a great pity that vaccination is being so sadly neglected in certain of these. Eastbourne shows a default of 70 per cent., Scarborough of 59·9 per cent., and Cheltenham of 38 per cent. Health-seekers who do not choose to take advantage for themselves and their families of the great protective power of revaccination cannot safely afford to neglect such figures as these, nor can they be neglected by medical men when consulted by patients as to the choice of a permanent or temporary place of residence. But the fact is that independently of health resorts, vaccinated or unvaccinated, the opportunities for attack by small-pox are likely now to increase so much throughout the country that it is the duty of every parent who cares for the welfare of those who are dependent upon him to see that he obtains for every one of them that protection which efficiently carried out vaccination and, where age renders it necessary, revaccination are so well calculated to afford.

NETLEY AS A SCHOOL FOR TROPICAL MEDICINE.

OUR readers have no doubt noticed in the controversial correspondence which has been going on regarding the proposed establishment of a school and hospital for the study of tropical disease in connexion with the Branch Seamen's Hospital that attention has been called to the advantages which the Netley Hospital and School afford in this respect. Although it seems to be assumed that the sanction of the War Office could not be obtained for the purpose no one, as a matter of fact, seems to have taken any steps to apply for it. Moreover, it is alleged that the Netley institution is unsuitable for the purpose; that it is too far from London; that the course of instruction followed there, however well adapted it may be to officers of the British and Indian Medical Services, is unnecessary and unsuitable for candidates for the Colonial Medical Service; and that in point of variety of cases illustrative of tropical disease it would not fulfil the necessary requirements. It seems to us that the last-named in the foregoing objections is the only one of any force. Let us, however, examine them a little more closely. The Royal Victoria

Digitized by Google

Hospital is a large military hospital to which sick and wounded soldiers are relegated from all parts of the world wherever soldiers are stationed and numerous cases of malarial disease in all its forms and dysentery are nearly always forthcoming, together with diseases of the liver including abscess of that organ. An excellent bacteriological laboratory, microscopes, and all appliances for the scientific investigation of disease are available, together with a pathological museum. Practical instruction is systematically given in the microscopical examination of the various fluids and tissues of the body, including of course the examination of the blood for the detection of the plasmodium malariæ. The instruction is afforded by men practically acquainted with tropical disease and there are always present and doing duty in the hospital wards medical officers who have had foreign service and experience in various parts of the world. Of course the distance of Netley from London would be prohibitory to its being used by residents in London, but why should not candidates for the Colonial Medical Service be required to go through a course of instruction in tropical medicine and remain at Netley whilst doing so? There is no reason, moreover, why such candidates should not confine themselves to this work without entering upon that connected with the more purely military course, unless they desired to do so in the direction of practical hygiene which would be very much to their advantage. If Netley Hospital does not offer all the varieties of tropical disease that could be desired it nevertheless affords a larger amount of tropical disease and more facilities for studying that subject than could probably be obtained elsewhere. For all those who were not seeking to enter the Colonial Medical Service but were desirous of practising in the colonies there would still remain open to them for clinical study the Seamen's Hospital at Greenwich and its Branch, as well as the metropolitan hospitals and such bacteriological laboratories as that at King's College. It is, we think, to be regretted that, instead of having years ago selected Netley as the site for our largest military hospital with its Army Medical School, London was not chosen for the purpose. The school might then have formed a teaching institution for a united medical service and for all medical officers in the employment of the State. The hospital and its attached school would then have been more largely available for all concerned and the hospital might have been fully utilised as such all the year round which is not, we believe, the case with the Royal Victoria Hospital at Netley. It is obviously too late, however, to think of this now; but that is no reason why its sphere of usefulness should not be enlarged and developed in the public interest and in that of the Government.

THE PLAGUE COMMISSION IN INDIA.

THE pressure on our space entailed by the "Annus Medicus" compels us to hold over the weekly letter from our Special Correspondent in India. But one piece of news in his communication is so interesting that we do not delay its publication. He writes under date Dec. 10th:—"The Commissioners sitting at Bombay on Dec. 5th examined Mr. R. H. Vincent, C.I.E., the Commissioner of Police. He stated that in the months of May, June, and July of 1896 a large number of Sadhus (ascetics) came to Bombay from Kumaon in the Himalayas and that they lived in Mandvie. They were subsequently sent by some rich Banias to Nassik, a holy place of pilgrimage for the Hindus. He stated that the mortality during their stay was very high and he was of opinion that the plague broke out in Bombay in July and not in September. This evidence is so extraordinary and has been so unexpectedly given that it has excited considerable comment. The facts have not been published before. That this information should have been kept dark for over two years and then made known by the head of the police in Bombay is passing strange, more especially as Dr. Weir's two annual health reports, Mr. Nathan's four-volume official report, and numberless minor contributions have all appeared without allusion to any particulars of such importance."

THE NATIONAL HEALTH SOCIETY AND PREVENTABLE DISEASE.

WE have received two little pamphlets written by Dr. Christopher Childs for the National Health Society. The one deals with typhoid fever and the other with tuberculosis. They set out in clear and simple language the precautions to be taken by those who have charge of persons suffering from any manifestation of the above diseases and in the case of tuberculosis reference is made to the necessity of keeping a strict watch over milk- and meat-supplies. If the average citizen can only be brought not only to read these instructions but also to act up to them the National Health Society may pride itself upon an eminently useful piece of work.

NORWICH MEDICO-CHIRURGICAL SOCIETY.

THE Medico-Chirurgical Society of Norwich has now been in existence for fifty years. It was originated in 1848 under the first presidency of Mr. John Greene Crosse with the name of the Norwich Pathological Society. After some years this was amalgamated with the Norwich Medical Book Society with the new name of the Norwich Medico-Chirurgical Society, under which title it now exists. The result of this amalgamation was that the members of the medical society became possessed of a large and very valuable library. This being the jubilee year of the society the president (Mr. W. E. Wyllys of Yarmouth) most hospitably invited its members to a banquet at the Royal Hotel, Norwich, on Dec. 8th to celebrate the occasion—an invitation which was accepted by seventy-eight gentlemen, including three of its honorary members—i.e., Dr. Robert Barnes, Mr. Richard Barwell, and Mr. A. Pearce Gould of London and two of the earliest members, Sir Peter Eade and Mr. W. Hankes Day. It may be mentioned that the Norwich Medico-Chirurgical Society has 136 members and it now includes almost the entire profession of Norfolk as well as many residents in Suffolk and adjacent districts.

THE PLAGUE ON THE "GOLCONDA."

A MILD case of plague is stated to have been discovered on the steamship *Golconda* at Plymouth on Saturday last. The *Golconda* is a British India Company's ship sailing from Calcutta and the case did not manifest itself until Marseilles was reached, a fact which is at variance with our usual theories concerning the incubation period of plague. Due precautions having been taken by the authorities the *Golconda* was allowed to proceed to London, where she underwent the usual processes of disinfection in such cases. The patient was left at Plymouth, the report current about his arrival in London as well as the statement that a second case was discovered on board being unfounded.

WE have received the Medical Directory for 1899. In a future issue we shall give a more detailed notice of this most useful work. We may, however, mention that the Directory for 1898 comprised 1936 pages, while that for 1899 comprises 1960 pages

THE annual banquet of the Worshipful Company of Plumbers, to meet the Lord Mayor and Sheriffs of the City of London, which was postponed on account of the death of

Digitized by Google

Sir Stuart Knill, has now been fixed for Wednesday, Jan. 18th. The guests will include the representatives of various sanitary and educational bodies and others who are in sympathy with the Company's efforts to promote the higher and more systematic technical instruction of plumbers.

QUACKS AND ABORTION:
A CRITICAL AND ANALYTICAL INQUIRY.

IV.[1]

AT the conclusion of the recent trial of blackmailers at the Old Bailey Mr. Justice Hawkins sentenced two of the infamous Chrimes brothers to twelve years' penal servitude and the youngest of them, who had possibly been led away by the elder ones, to seven years' penal servitude. Their case, as we have already pointed out, exemplifies in a strikingly complete manner the evils which may result from the advertisements that drew our attention to the trade in "female remedies" and caused us to commence our inquiry into its methods.

More particularly the case proved beyond all doubt, firstly, that very nearly all the persons who buy medicines advertised for "irregularities" buy them in the hopes that by their aid they will be enabled to procure abortion. This is clearly shown by the vast number of women who allowed themselves to be blackmailed without any attempt at resistance. Certainly in cases of blackmail innocent, or comparatively innocent, people who have placed themselves in compromising circumstances pay to avoid publicity or some charge not obviously easy to refute; but no one can believe that the most ignorant woman suffering from amenorrhœa, neither pregnant nor having incurred the risk of pregnancy, would submit to extortion because she had taken an emmenagogue mixture or would believe that to take such a mixture was a criminal act. The mass of women having guilty consciences who sent money to "Charles J. Mitchell, Public Official," bears out our observations as to the small number of women who could possibly desire to bring on menstruation if those pregnant were eliminated. Secondly, we have repeatedly referred in these articles to the fact that it was the ignorant whom the trade in abortifacients, or pretended abortifacients, was likely to tempt into crime. Ingeniously worded as the letter of the Chrimes brothers undoubtedly was, few but the ignorant, guilty or not, would have imagined that "Charles J. Mitchell, Public Official," was an officer of the law trying to extort money by virtue of his official power. Thirdly, we have spoken of the enormous trade done in these concoctions. In the course of the trial of the Chrimes brothers it was elicited that thousands of pounds had been spent on advertisements. Sir Henry Hawkins drew attention to the fact that £800 had been received in three or four days (including presumably blackmail and purchase money), while a letter-box put up expressly by the prisoners at one of their offices was produced in court which must have contained at least 6 or 7 cubic feet of space to accommodate their correspondence. Fourthly and most obviously, the case illustrates the dangers of blackmail connected with this trade which we have already stated must exist. It is difficult to prove the prevalence of blackmail for obvious reasons, but it is known to be a means of livelihood for many persons in London and elsewhere who are never convicted, and we believe it to be an important source of income to most of those persons who carry on businesses connected with sexual vice, such as, for example and not to exhaust the list, indecent exhibitions, the sale of alleged cures for defective virility, and so-called massage establishments.

The more prudent offenders escape—for a time at any rate. It was not their attempts at blackmail that brought the Chrimes brothers to trial but their wholesale and reckless adoption of it. Threatening, as they apparently did, all the hundreds of women who had purchased goods from them, they naturally lighted on some innocent of any wrong design in purchasing the medicine and of sufficient education and courage to see that their only safe and prudent course was to inform the police. We conclude our comment on this case by printing one of the advertisements which was before us when we began our inquiry through which we should in due course have opened up a correspondence with the Chrimes brothers had not their arrest rendered this unnecessary:—

Acknowledged by Ladies throughout the World to be worth a Guinea per Tabule.

LADIES ONLY.

THE "LADY MONTROSE"

MIRACULOUS

FEMALE TABULES

Are positively unequalled for all FEMALE AILMENTS. The most OBSTINATE Obstructions, Irregularities, etc., of the female system are removed in a few doses. Being SPECIALLY prepared, they are guaranteed STRONGER in action than the strongest (or "No. 2" and "3") LIQUID Female Mixture, Pill, or Fluid Medicine on earth. Failure is impossible. Post free, under cover, with full directions and advice 4s. 6d., with SWORN EVIDENCE as an absolute guarantee enclosed in every case. One case sufficient. A special and valuable OUTWARD Remedy sent free.

A FEW TESTIMONIALS FROM MANY THOUSANDS.

"Am overwhelmed with delight to say that your miraculous (for miraculous they are) Tabules painlessly restored regularity before taking one quarter of a box."—Mrs. N., Long-lane, Orford, Warrington.

"After taking the last dose late Saturday night I was quite well early Sunday morning."—Mrs. C., Mount Pleasant, East Hill, Dartford.

"I heard from my sister, Mrs. Weentell, to say they had proved successful. She is exceedingly grateful."—Mrs. H., Northern Hospital, London.

"The Tabules you sent were marvellous. I was advised by a friend who had been relieved herself after a few doses. Mine being a case of MONTHS, I tried a box, and after taking a few doses I was astounded to find myself relieved. I had spent a great deal in 'FAMOUS' FEMALE MIXTURE, etc., but only had pain and no relief. I enclose 4s. 6d. for another box for another lady friend."—Mrs. L., Merton-street, Huddersfield, Yorks.

THE ABOVE TESTIMONIALS (AND THOUSANDS OF OTHERS) ARE EACH SEEN AND SWORN TO, UNDER OATH, BEFORE ONE OF HER MAJESTY'S COMMISSIONERS FOR OATHS, TO BE TRUE AND GENUINE.

Don't delay. Send To-day for full particulars, and absolutely Conclusive Proofs. Be cured without trouble and expense with these startling Tabules. Address, H. A. N. MONTROSE, 64, Imperial Buildings, Ludgate Circus, London.

CAUTION.—Don't waste money on useless "Famous," "Important," etc., Fluid mixtures, Cones, "Without Medicine" Remedies, "Indispensable" Pills, etc. It is utterly impossible for these weak "Water and Medicine," etc., Remedies, to be as strong as my powerful, irresistible Compressed Tabules, and I have a Certificate GUARANTEEING these Tabules.

It will be seen that the above advertisement differs in no material respect from the examples that have afforded the materials for the rest of our inquiry. Like many of the other advertisements—as, for instance, that of Ottey—it says nothing of the more expensive medicines to be urged upon the victim when once communication is established. Like that of the vendor of Irristum it seeks to dupe the credulous with a statement that the testimonials are sworn on oath to be genuine. Its testimonials are of the same pattern as those concocted by other vendors. If the purchasers of H. A. N. Montrose's tabules fell easy victims to the blackmailer, those who buy from any other persons carrying on the same trade have been and will be always in danger of blackmail also. We remind our readers that in our first article we alluded to an advertisement received from a quack to whom we had not written and who alleged, no doubt truly, that he had bought our name and address (which was not the name of this journal or the address of this office) from one of the others to whom we had written. The bearing of this transaction on the danger of blackmail is so obvious that no further comment upon it is needed. We now conclude our analyses of the various pills and potions for which we applied.

H

The advertisement in this case was as follows:—

Dodd's Female Pills.—The Proprietor, who was for several years at THE HOSPITAL FOR WOMEN, SOHO, LONDON, has never known them to fail in removing the most obstinate cases of IRREGULARITIES in either MARRIED or SINGLE WOMEN. REMARKABLE TESTIMONY. 95,000 Boxes of these Wonderful Pills were sold last year through recommendations alone of NURSES and PATIENTS of THE HOSPITAL FOR WOMEN.

In Boxes 1s. 1½d., 2s. 9d., 4s. 6d., and 11s. each, of all Medicine Vendors. ASK for DODD'S. INSIST ON HAVING DODD'S. Or post free from JEFFERSON DODD, CHEMIST. CHIEF DEPOT: 70, Tottenham Court-road, London, W. Branch Depot: 123, Judd-street, W.C., near King's Cross.

Our letter represented the writer as desiring a box of pills for an "obstinate case," as being an unmarried woman, a

[1] Articles I., II., and III. were published in THE LANCET of Dec. 10th, 17th, and 24th, 1898, respectively.

Digitized by Google

servant, while it further asked for the pills to be packed secure from observation. As a matter of fact they arrived in a General Post Office envelope, that in which they were originally despatched having burst in the post. The advertisement sheet accompanying them referred largely to Mr. Dodd having been connected with the Hospital for Women, Soho-square. It stated among other things that "Dodd's Female Remedies are recognised by the most eminent medical authorities in London on Diseases of Women as being the safest and most beneficial Medicines that science, skill, and long years of practice have been able to discover for the cure and relief of complaints peculiar to the Female Sex." We note that Mr. Dodd states that 95,000 boxes of his pills were sold last year through recommendations alone of nurses and patients of the Hospital for Women. We think the authorities of the hospital in question would be well advised to try conclusions with Mr. Dodd as to his right thus to use the name of their institution.

Analysis of DODD'S FEMALE PILLS.

Moisture, 6·3 per cent.
Organic substances, 38·8 per cent.
Mineral matter, 54·9 per cent.

As will be seen these pills contain more than half their weight of mineral matter which was found to consist chiefly of iron. On incinerating, however, the pills in a platinum basin a marked green flame occurred characteristic of boron compounds.

The alcoholic extract yielded several well-marked reactions characteristic of aloes.

On treatment with potash an odour like myrrh was noticed. There was no evidence of poisonous metallic salts.

The important constituents, then, of these pills are iron, aloes, and probably borax. With regard to the second it should be mentioned that already this year evidence has been given at an inquest to the effect that a woman had been poisoned by the enormous purgative doses of aloes that she had swallowed in taking so-called Female Pills. With regard to the indications of borax present we have only to quote Squire's Companion to the British Pharmacopœia where borax is classified as an ecbolic "which promotes the contraction of the uterus and facilitates the expulsion of the contents."

I

The following is the next advertisement which attracted our attention. We may find space to discuss hereafter the extent to which it is the duty of proprietors or editors to consider the nature of the advertisements appearing in their papers and the extent of their power to detect objectionable qualities in the trade advertised from the advertisements themselves without further inquiry or recourse to extraneous sources of knowledge. We submit, however, to the good sense of our readers that to call such notice as that we now print "suggestive" would be to employ an unnecessarily mild term to it.

AN HONEST MEDICINE.

Dr. Davis's Famous Female Pills. Pearl-coated and Tasteless. Most efficacious and reliable. No Irregularity or Obstruction can resist them. They possess a world-wide reputation as A BOON TO WOMANKIND.

In boxes 9½d., 1s. 1½d., 2s. 9d., and 4s. 6d. Prepared only by Dr. Davis, 309, Portobello-road, London, W., by whom they will be forwarded free from observation on receipt of Postal Order, or order of any Chemist.

SENT FREE.—Dr. DAVIS'S little Book for Married Women most invaluable, on receipt of a Stamped Addressed Envelope.

These pills were among the least expensive we have had experience of in our inquiry, for we selected those at 9½d. per box and ordered them in the usual terms, asking for secrecy, the purchaser being represented as a servant. We referred in our first article to a printed slip which accompanied these pills when we received them; from it we learn that "Dr. Davis" compounds them of varying strengths, some proclaimed to be of "Special Strength" being priced at £1 2s. He states that he gives advice free on certain evenings and says in a note that "these Pills must not be taken by those expecting to become mothers." He also says: "Dr. Davis's Famous Female Pills are the greatest preventive in the world; they should be taken four or five days before every month." He further marks as "very important" a warning that his pills "are not intended, and should not in any case purge," and he appends an advertisement of a book entitled "How to Limit your Family and Woman her Complaints." The analysis of what he sent us is as follows; we did not correspond with him further or test his pills of extra strength at £1 2s.

Analysis of "Dr." DAVIS'S PILLS.

Moisture, 9·75 per cent.
Organic substances, 56·25 per cent.
Mineral matter, 34·00 per cent.

As in most other cases, the mineral residue was practically all iron. On employing solvents with the pills residues were obtained which gave a good response to the reactions characteristic of rhubarb. The pills contained also an aromatic substance with a smell resembling oil of roses. Neither mercury nor arsenic was detected.

J

The next advertisement to which we replied ran as follows:—

DR. HESELDINE'S FEMALE PILLS

Never fail in removing the most obstinate cases of irregularity or obstruction, from whatever cause, as a rule in a few hours. Boxes 7½d., 1s. 1½d., and 2s. 9d. Extra strong 4s. 6d. Post free. Obtainable only from 118, FALCON ROAD, CLAPHAM JUNCTION, LONDON.

Our letter represented the sender as in domestic service and asked for a box of pills at 7½d. packed so as to be safe from observation. We give below the analysis of the contents of the pills which we received in reply. The box, it may be mentioned, bore the Revenue stamp, as did also the boxes of "Dr." Davis and Mr. Dodd. This stamp is believed by many ignorant purchasers to be a sort of Government certificate of favourable official recognition or guarantee of the medicine that it accompanies, while, needless to say, it in no way whatever guarantees or recognises anything. For instance, in the case of "Dr." Heseldine's pills the Inland Revenue officials, representing the Chancellor of the Exchequer, presumably do not claim to be aware that their stamp is affixed to pills which "never fail in removing obstruction from whatever cause" and are of such a nature that the vendor encloses the following caution with them:—"These medicines though quite harmless in their operation are most powerful in their effects and must not be resorted to for illegal purposes nor on any account be taken by ladies desirous of becoming mothers." The analysis below will enable our readers to judge whether this is a genuine caution or whether it merely exaggerates the qualities of the pills with a view to inducing pregnant women to purchase them. We note that the vendor says, "Prevention is better than cure; Dr. Heseldine's pills are the greatest preventive in the world," and that the rest of the literature accompanying the box sent to us dealt mainly with the merits of various mechanical means for preventing conception similar to those referred to in other cases.

The analysis of the pills is as follows:—

Analysis of "Dr." HESELDINE'S FEMALE PILLS.

Moisture, 7·71 per cent.
Organic substances, 75·99 per cent.
Mineral matter, 16·30 per cent.

The mineral matter contained both iron and an alkaline carbonate so that it is probable that these pills were made up partly on the basis of a Blaud's pill. The organic extract gave no evidence of any aperient substance being present other than aloes. Mercury and arsenic were carefully tested for but without the slightest positive indication.

The pills had a characteristic smell suggesting valerian.

K

The advertisement in this case was printed in our first article. It was as follows:—

Apiol and Steel Pills for Ladies.—A French Remedy for all Irregularities. Obtainable only from Martin, Chemist, Southampton. Price 4s. 6d., post free.

Our letter stated that the writer was a servant, enclosed 4s. 6d., and asked for the pills as advertised to be sent packed secure from observation. They duly arrived with printed advertisements of other goods sold by the same chemist, the pills themselves figuring on a piece of paper which also extolled "Dr. Fournier's Soluble Preventive Cones, Introduced and recommended by the late Dr. Fournier, a celebrated Parisian lady specialist." Beneath further details of this invention the medicine we have analysed is described as "Apiol and Steel Pills, the French

Digitized by Google

Remedy for Irregularities." On a separate slip of paper is recommended "For Obstinate Cases of Female Irregularity" a "Hygienique Mixture, Dr. Fournier's Formula at 11*s*." From these announcements must be inferred the purpose for which these pills were advertised; the extent to which they are calculated to fulfil the promises of their vendor will be appreciated by those who study their analysis below.

Analysis of MARTIN'S APIOL AND STEEL PILLS.

Moisture, 5·00 per cent.
Mineral matter, 34·21 per cent.
Organic substances, 60·79 per cent.

These pills are described as steel and apiol pills. They are pink in colour which is due to the use of a fluorescent aniline dye.

The mineral matter consisted almost exclusively of iron. There was no satisfactory evidence of the presence of, at any rate, any important quantity of apiol. On distillation a trifling quantity of oil was obtained possessing a smell suggestive of apiol. Ether also extracted a small quantity of oil which had a parsley-like odour. Very satisfactory evidence was obtained in favour of the view that these pills contain more aloes than anything else.

The case of the Chrimes brothers has demonstrated the possibility that blackmail may be associated with traffic in these abortifacients and so-called "preventive" remedies. The crime, however, is so serious and entails with universal applause such severe penalties upon the criminal that it possibly has not been common. But another contingency presents itself forcibly for consideration and that is that the advertisements can be made the medium for simple robbery. The circumstances attending our communications with Madame Frain suggest to us that this may have occurred frequently. Madame Frain is an individual who advertises largely, or was wont to do so when these articles were commenced. Here is the specimen of her advertisement which attracted our attention:—

Ladies. — Absolutely Indispensable to LADIES! Particularly those who desire a quick, safe and reliable and non-injurious remedy for all obstructions and irregularities, a medicine which cures (usually in a few hours) cases which have baffled the skill of the best medical men. No lady need despair, as the most obstinate and helpless cases have been immediately relieved by this remedy. Mrs. Wilson, of Honor Oak Park, Forest Hill, says: "Your invaluable remedy took immediate effect; in less than 12 hours I was all right, after 18 weeks of misery and hopelessness." A properly certified guarantee is enclosed with testimonials and medicine. One package at 4/6 is usually sufficient for any case. Ladies send at once fully directed envelope for particulars and proofs. I will forfeit £2,000 if the testimonials are not genuine. Thousands of unsolicited testimonials have been received. Do not be misled by showy advertisements and other so-called remedies which are utterly worthless and *fraudulent* imitations.

NOTICE.—This wonderful remedy guaranteed to have the largest sale in the entire world, being the oldest and only harmless medicine of its kind for ladies, and cures more patients in one month than all other Female Remedies put together in twelve months. This can be proved by our Testimonials.

If you require more particulars I will send you per return of post, in sealed letter, post free, a splendid Book (34 pages) and Guide (cloth covers, 60 pages and 40 illustrations of Ladies' Appliances), and full particulars of the wonderful effective remedies as advertised and sold in every town and village in Great Britain. Consultations Free every day 3 to 7. Established over 100 years.

Do not delay, but write at once privately to Madame FRAIN, Medical Institute, Hackney-road, London, N.E. (opposite Shoreditch Church).

In replying to this advertisement after receiving preliminary particulars we wrote on Nov. 19th to Hackney-road for a bottle of the "Strongest Mixture" and a box of pills and we enclosed a postal order for 15*s*. We received no reply and no goods. We therefore wrote again on Nov. 29th complaining of their non-receipt to which letter we received the following reply:—

Telegrams—Frain, Hackney-road, London.
Bankers—London & Midland.
Herbal Institute, 1a, Hackney-road (opposite Shoreditch Church), London, N.E., Dec. 1st, 1898.

MY DEAR MADAME,—I am very sorry your letter has been overlooked, Kindly write stating full particulars what you require and how much money was enclosed in your letter.

And oblige, yours faithfully,
MADAME FRAIN.

To this letter we replied on Dec. 2nd repeating our request for the bottle of "Strongest Mixture" and a box of pills, and pointing out that a postal order had been sent. From that day to this we have heard nothing from Madame Frain. The train of conclusion is obvious. The wording of Madame Frain's advertisements clearly invites communications from unchaste women. The enormous majority of women with amenorrhœa are *enceinte*, and another large class of persons who would be allured to answer Madame Frain are the persons who place themselves in the position of being *enceinte* and who fondly think that by swallowing preventive nostrums the processes of procreation may be fended off. How are these unfortunate women, having sent money to Madame Frain and having received no reply, to compel her to send it back? Some perhaps know that the purpose for which they sent the money was illegal; others without much respect for the law still regard very highly the opinion of their friends or their employers. How can they ask the police to assist them in making Madame Frain disgorge and yet preserve their secrets? The calm proceeding of keeping our postal order (the number of which we warn this predatory matron we have noted) is what might have been expected from the literature disseminated by the Herbal Institution (or Ladies' Medical Institution, to give the shop its alternative title) in the Hackney-road, for everything about Madame Frain's methods reeks of fraud. In her first reply to us she posted us a bundle of testimonials "from ladies selected from all parts" and adds that she has "thousands of others which I will gladly show and will forfeit £2000 if the testimonials are not absolutely genuine." We will excuse Madame Frain from paying us the £2000, not out of any consideration for her but solely out of consideration for the vile origin of her money; nevertheless the testimonials are not genuine. It is true that the envelope in which they were enclosed bears the following inscription:—

Personal & Private.

DEAR MADAME,

To demonstrate beyond doubt the effecacy of our Female Mixture & Pills I am enabled to enclose herewith for your perusal *in Strictest Confidence* a few testimonials (among many thousands which can be seen at any time by you in their post-marked envelopes) of Ladies who have *unsolicited* acknowledged their marvellous unequalled and unfailing effect I know I may rely upon *your honour to immediately post the enclosed back to me after perusal* for which I enclose a directed envelope.

Trusting this will satisfy you as to our *Bona Fides* and referring you to the book of printed testimonials also enclosed

Yours very faithfully,
M. C. FRAIN.

Alas for Madame Frain's *bona fides!* All the original "testimonials" which she relied on our honour to return to her are lithographs. They are reproduced on different coloured paper in different coloured inks and if in some cases different handwritings are obvious in others their similarity is striking; but the documents are merely lithographs of the sort that can be turned out by the thousand.

We shall publish no more analyses of pills and potions. We have now made known the constituents of the most widely advertised nostrums and on the basis of the knowledge thus derived shall be able later to discuss some of the broader issues opened up by our articles.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

THE forty-second meeting of this Commission was held on Monday, Dec. 19th, when Lord LLANDAFF (chairman) presided, and the other Commissioners present were Sir George Barclay Bruce, Mr. Cripps, Q.C., Mr. de Bock Porter, Major-General Scott, and Mr. Robert Lewis. The entire sitting was devoted to the examination of Mr. Charles Hawksley, C.E.

Mr. HAWKSLEY, in reply to the CHAIRMAN, said that he had had considerable experience in the designing and construction of waterworks both for companies and for local authorities. He was in partnership for upwards of twenty-five years with his father, the late Mr. Thomas Hawksley, C.E., who first introduced into this country the system of constant supply. His father and Sir Frederick Bramwell in 1892 considered and approved the proposals of Messrs. Hunter and Fraser for the storage of Thames water at Staines and gave evidence in support of them before the Balfour Commission. Subsequently Sir Frederick Bramwell and the witness were consulted in reference to, and they approved of, the scheme embodied in the Staines Reservoirs Bill which received the sanction of Parliament in 1896 and he and others had been requested by the London water companies to give evidence before this Commission. In preparing the various tables which he now presented he had taken the

Digitized by Google

growth of population at the rates suggested by the Balfour Commission of 18·2 per cent. per decennium for Greater London and 19·7 per cent. per decennium for the outlying parts of Water London. The result was that in the case of Greater London the population was estimated to increase from 5,656,909 in 1891 to 13,043,712 in 1941 and in the case of the outlying parts from 76,041 in 1891 to 187,504 in 1941. Witness explained that there are no official figures to show how far the estimate of the growth made by the Balfour Commission has been borne out by experience, but he did not believe it would be found far amiss. He felt certain that the figures given by the Commission are perfectly safe for the purposes of calculation. The average daily supply from all sources for the year 1897 amounted to 202,102,544 gallons, made up as follows:—From the River Thames 112,178,641 gallons, from the River Lee 55,292,863 gallons, from springs and wells 34,488,016 gallons, and from ponds at Hampstead and Highgate 143,024 gallons. The witness presented a table showing the quantity of water to be provided in the future by the eight London companies and by other companies and local authorities deriving their supplies from the basins of the rivers Thames and Lee to meet the requirements of the estimated population of Greater London and the outlying parts of Water London during the period up to 1941. In this calculation Mr. Hawksley took 35 gallons as the daily quantity of water required per head of the population and the results he worked out were:—

	Estimated population.	Gallons required per day.		Estimated population.	Gallons required per day.
1891 ...	5,733,000	... 200,655,000	1921 ...	9,468,000	... 331,380,000
1901 ...	6,777,000	... 237,195,000	1931 ...	11,192,000	... 391,720,000
1911 ...	8,010,000	... 280,350,000	1941 ...	13,231,000	... 463,085,000

Witness explained that the object of introducing 1891 was to get a starting-point which was familiar, although as a matter of fact 35 gallons per head of the population were not supplied in that year.

Major-General SCOTT reminded Mr. Hawksley that the reference of the present Royal Commission deals only with the eight metropolitan water companies and their responsibilities, while the calculation he now put forward was much wider in its scope.

Mr. HAWKSLEY, admitting this, said that the Balfour Commission intimated that inasmuch as the water for the other districts must be obtained from the same sources as those which supplied the metropolitan companies they ought to be considered in determining the effect on the Thames or the Lee. Continuing his evidence Mr. Hawksley said that to meet this quantity required the Balfour Commission considered that they might reckon on 52½ million gallons per day from the River Lee, 40 million gallons from wells in the Lee Valley, and 27½ million gallons from wells in the Kent Company's district—a total of 120 million gallons per day. Accepting these figures they left 343 million gallons to be obtained from the Thames or from wells in the Thames Valley to meet the estimated daily requirement of 1941 and witness was decidedly of opinion that the Thames could yield this without reaching the limit of its capabilities. He had given the matter very careful attention and he was of opinion that it could yield a great deal more than this quantity. In the Thames Valley there were a great many convenient sites for reservoirs.

Mr. PORTER: Then you think it is idle to look elsewhere than the Thames?

Mr. HAWKSLEY: Yes, within the period to which we need look forward at the present moment. If you speak of 500 years hence, that, of course, is another matter, for when we have used up all available water in the Thames we must go elsewhere.

Mr. PORTER: Would you say that for the next 100 years at all events, it is not necessary to go to Wales?

Mr. HAWKSLEY: I do not think it is.

The CHAIRMAN: You think it is an unnecessary precaution at the present time?

Mr. HAWKSLEY: I think so.

The CHAIRMAN: Would you wait till another party brought in a Bill to appropriate the water?

Mr. HAWKSLEY: I would wait till there was talk of appropriation.

In reply to Major-General SCOTT witness said that the Staines reservoir scheme contemplated a total extent of 6000 acres.

Major-General SCOTT: That is to say nearly 10 square miles.

The CHAIRMAN: Ten square miles of water in the neighbourhood of Staines!

Mr. PEMBER, Q.C.: That is nothing to a flood.

Mr. HAWKSLEY: No. And it would not do the damage that a flood does; it would not go into the people's houses.

In further examination Mr. HAWKSLEY said that in his opinion much more than the 343 million gallons per day might with propriety be taken from the Thames. He had not fixed a limit but any limit he might fix would have for its basis the flow over Teddington Weir and the financial considerations governing storage. His opinion was that the flow over Teddington Weir might very properly be reduced to 100 million gallons per day or even to a smaller quantity in exceptional years. He was not prepared to give a description of what the river below would be like if only 100 million gallons passed over the Teddington Weir. Witness presented a series of figures making a comparison of the cost of the Thames and the Welsh schemes. They showed he said, that up to the year 1941, the accumulated expenditure in respect of interest on capital would in the case of the Welsh scheme, even when reckoned on Sir Alexander Binnie's own estimate, have exceeded the corresponding accumulated expenditure in respect of interest on capital and cost of pumping in the case of the Thames scheme by the sum of £5,464,179 and that thenceforward the expenditure on the Welsh scheme would exceed the corresponding expenditure on the Thames scheme by the sum of £28,373 per annum to be borne in perpetuity. The next point taken up by Mr. Hawksley was the comparative merits of company and corporation management. His experience, he said, extended to both systems and he had no hesitation in saying that water management was generally better in the hands of a company than in those of a corporation. A company was not subject to being influenced by political considerations which was generally the case with a public authority, and it looked at the matter from a more solid and commercial basis than was done by a public authority. In addition public authorities were swayed not only by politicians but also by faddists.

The CHAIRMAN: Is it not your experience that corporations and public bodies which have acquired the water-supply have ultimately reduced the charge to the consumer.

Mr. HAWKSLEY: Not usually until a considerable period has elapsed and then there have been instances where there has been a reduction.. In the meantime, however, there has frequently been a large loss incurred. Witness proceeded to cite the experience of such places as Heywood, Rochdale, and Middlesbrough, where there has been a transference of the water undertaking from a company to the public authority and where after the tranference there have been applications to Parliament for power to increase the rates charged to consumers. He also cited several cases where grants in aid have been found necessary.

In reply to Mr. PORTER witness said he did not doubt that many of these water undertakings were capable of being ultimately worked at a profit by the corporations. He was not prepared to say that he knew any corporation which would like to go back to company management. Quite apart from results corporations were not likely to give up the power and patronage involved and the prestige. As to whether the consumers if polled would declare in favour of a return to company management it was difficult to say because the consumers seldom understood these matters.

Mr. PORTER: But surely the consumers know whether they are paying more or less for their water?

Mr. HAWKSLEY: The consumer does not find that out.

The CHAIRMAN: I suppose you recommend all your public authority clients to turn over their concerns to private companies?

Mr. HAWKSLEY: That would not suit the corporations. It would be of no use giving such advice because they could not sell their undertakings at a price which would make it remunerative to a company to buy and they would not like the loss of prestige.

The CHAIRMAN: Does the management of a water undertaking bring prestige? I thought it only brought abuse.

Mr. HAWKSLEY: Yes, I think there is some prestige.

The CHAIRMAN: You dropped a hint about patronage.

Mr. HAWKSLEY: Yes, a corporation employs a large staff of men in connexion with its waterworks.

Mr. PORTER: Can you give a case apart from London where you think things are better in the hands of a company than they would be if transferred to the municipality?

Mr. HAWKSLEY: Yes; I can give Norwich, Yarmouth,

Digitized by Google

Lowestoft, Bristol, Sunderland, and others, and of course I think London would be much worse off.

The usual time for adjournment having arrived the CHAIRMAN announced that the Commissioners proposed meeting on the following day and further examining Mr. Hawksley.

Mr. HAWKSLEY explained to his lordship that he had an important arbitration case to attend on that day.

The CHAIRMAN, addressing counsel for the companies, asked whether they had any other witnesses to tender.

Mr. POPE, Q.C., said that Mr. Eaton was prepared to give evidence.

The CHAIRMAN said that so far as he could gather Mr. Eaton proposed to do nothing more than corroborate Mr. Hawksley and he would remind the companies that the main question after all was the question of financial expediency. Long ago certain statements had been made as to the capital of the companies and he should have expected to find them eager to meet these statements. If the companies did not have their evidence ready the Commissioners would have to proceed with something else.

Mr. POPE assured his lordship that his clients had no desire to keep back evidence.

After some further conversation it was decided that the Commission should not meet again until Monday, Jan. 9th.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6169 births and 3830 deaths were registered during the week ending Dec. 24th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 19·1 to 16·6 per 1000, rose again last week to 17·8. In London the rate was 17·0 per 1000, while it averaged 18·3 in the thirty-two large provincial towns. The lowest death-rates in these towns were 10·6 in Cardiff, 12·4 in Wolverhampton, 12·5 in Leicester, and 13·8 in Croydon; the highest rates were 22·1 in Liverpool, 23·0 in Manchester, 25·4 in Salford, and 30·2 in Swansea. The 3830 deaths in these towns included 424 which were referred to the principal zymotic diseases, against 399 and 372 in the two preceding weeks; of these 115 resulted from diphtheria, 104 from measles, 70 from "fever" (principally enteric), 53 from whooping-cough, 50 from diarrhœa, and 32 from scarlet fever. The lowest death-rates from these diseases were recorded in Croydon, Leicester, Derby, and Burnley, and the highest rates in Leeds, Nottingham, Bolton, and Swansea. The greatest mortality from measles occurred in Manchester, Salford, Bolton, and Nottingham; from whooping-cough in Halifax and Boston; and from "fever" in Salford, Bolton, Brighton, and Norwich. The mortality from scarlet fever showed no marked excess in any of the large towns. The 115 deaths from diphtheria included 46 in London, 17 in Leeds, 10 in Swansea, 7 in Sheffield, 6 in West Ham, 6 in Liverpool, and 4 in Brighton. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylums Hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital on Saturday last, Dec. 24th, was 2901, against 3142, 3099, and 3043 at the end of the three preceding weeks; 221 new cases were admitted during the week, against 264, 276, and 260 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 295 and 283 in the two preceding weeks, were last week 284, and were 195 below the corrected average. The causes of 52, or 1·4 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Cardiff, Leeds, Hull, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Huddersfield, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·0 and 19·4 per 1000 in the two preceding weeks, further declined to 18·2 during the week ending Dec. 24th, but slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·6 in Leith and 15·2 in Paisley to 21·1 in Aberdeen and 22·1 in Perth. The 549 deaths in these towns included 14 which were referred to scarlet fever, 14 to whooping-cough, 13 to diarrhœa, 12 to measles, 11 to "fever," and 4 to diphtheria. In all, 68 deaths resulted from these principal zymotic diseases, against 71 and 64 in the two preceding weeks. These 68 deaths were equal to an annual rate of 2·3 per 1000, which was 0·3 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of scarlet fever, which had increased from 3 to 12 in the four preceding weeks, further rose to 14 last week, of which 9 occurred in Glasgow and 2 in Dundee. The 14 deaths from whooping-cough were within 2 of the number in the preceding week, and included 9 in Glasgow, 2 in Paisley, and 2 in Dundee. The fatal cases of measles, which had declined from 19 to 8 in the three preceding weeks, rose again to 12 last week, of which 6 occurred in Glasgow, 3 in Edinburgh, and 3 in Aberdeen. The 11 deaths referred to different forms of "fever" exceeded by one the number in the preceding week, and included 8 in Glasgow and 2 in Edinburgh. The deaths from diseases of the respiratory organs in these towns, which had been 163 and 132 in the two preceding weeks, further declined to 119 last week, and were 30 below the number in the corresponding period of last year. The causes of 30, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the three preceding weeks from 31·6 to 25·2 per 1000, was again 25·2 during the week ending Dec. 24th. During the past four weeks the rate of mortality in the city has averaged 27·0 per 1000, the rate during the same period being 17·1 in London and 21·3 in Edinburgh. The 169 deaths registered in Dublin during the week under notice corresponded with the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against 8 and 15 in the two preceding weeks; of these, 4 resulted from whooping-cough, 3 from diarrhœa, 2 from scarlet fever, 1 from "fever," and not one either from small-pox, measles, or diphtheria. These 10 deaths were equal to an annual rate of 1·5 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 3 and 5 in the two preceding weeks, declined again to 4 last week. Two deaths resulted from scarlet fever, against 1 in the preceding week; while the mortality from "fever" was below that recorded in any week since August last. The 169 deaths in Dublin last week included 37 of infants under one year of age and 38 of persons aged upwards of sixty years; the deaths of infants exceeded those recorded in the preceding week; while those of elderly persons showed a decline. Nine inquest cases and 7 deaths from violence were registered; and 63, or more than a third, of the deaths occurred in public institutions. The causes of 13, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointment is notified:—Staff Surgeon C. J. Mansfield to the *Pearl*.

ROYAL ARMY MEDICAL CORPS.

Colonel E. Townsend takes over the duties of the Principal Medical Officer of Her Majesty's Forces in India pending the arrival of Surgeon-General Taylor, C.B. Major R. Stuart is directed to proceed from Poona to Bombay for temporary duty in the Colaba Station Hospital. Lieutenant G. S. Nickerson has been appointed for service with the Egyptian Army. Captain H. J. M. Buist shortly proceeds to Woolwich. Surgeon-General W. A. Catherwood is appointed Principal Medical Officer, Bengal Command.

Digitized by Google

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant John K. Tomory, 1st Sutherland Highland Rifle Volunteers, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Cheshire and Carnarvonshire: Surgeon-Lieutenant John Oldershaw resigns his commission and is appointed Captain. The Highland: George Wilson to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Suffolk Regiment: Surgeon-Major M. E. Ling resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: John William Logie to be Surgeon-Lieutenant.

DEATHS IN THE SERVICES.

A correspondent writes:—The news was received in Plymouth last week of the death of Surgeon-Lieutenant-Colonel James Powell, M.R.C.S. Eng., L.R.C.P. Edin., R.A.M.C., which occurred on Dec. 17th on board the transport ship *Simla* while on his way to India. He was born in 1851, received his medical education at King's College Hospital, London, and took the qualifications of M.R.C.S. Eng. and L.R.C.P. Edin. in 1873 and 1874 respectively. In the latter year he entered the army and became Surgeon-Major in 1886 and Surgeon-Lieutenant-Colonel in 1894. Surgeon-Lieutenant-Colonel Powell was with the Natal Field Force in 1881 in the Transvaal Campaign and and in 1884–85 with the Soudan Expedition on the Nile when he was in charge of the Kaibur Field Hospital, and in 1885–86 with the Frontier Field Force when he took part in the action of Kosheh. In the military operations of 1885–86 he obtained mention in despatches and for the preceding campaign he received the medal with clasp and the Khedive's bronze star.

Deputy Inspector-General Duncan MacRae, retired list, Indian Medical Service, at Kames Castle, Bute, on Dec. 14th, in his eighty-third year. He joined the Honourable East India Company's service in January, 1839, served through the Afghan campaign of 1842, and was present at the capture of the fort of Khythul in 1843. He also served with the Bugti campaign in Scinde in 1846 and the Punjab campaign in 1848–49, including the siege of Mooltan and the battle of Goojerat. He was in the Indian Mutiny of 1857–58, and was present at Umballa, Meerut, and the capture of Delhi (three medals and three clasps).

Fleet Surgeon W. E. O'Brien, retired, at Dublin recently, aged seventy-six years. He joined the service in 1846, became Staff Surgeon in 1856, Fleet Surgeon in 1871, and retired in 1875.

REVISED REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS.

Revised regulations for admission to the above corps have been issued by the War Office. Candidates for appointment to the corps must be not under twenty-one and not over twenty-eight years of age at the date of commencement of the competitive examination. They will be required to produce an extract from the register of their birth or a declaration made before a magistrate by one of their parents, a recommendation from a person in society as to their habits, &c., and a certificate of moral character from a clergyman. They will also be required to produce two diplomas or licences recognised by the General Medical Council, one to practise medicine and the other surgery, and they must be registered under the Medical Act. They must also produce certificates of having discharged the duties of medical clinical clerk for six months and one of having attended a course of at least three months in an ophthalmic hospital. There will be two competitive examinations each year. Captains of the Royal Army Medical Corps serving in India will in future be allowed to undergo short courses of operative surgery at the medical colleges at Calcutta, Madras, and Bombay under arrangements just made by the Government of India.

THE INDIAN PLAGUE COMMISSION.

Touching the constitution of the Commission appointed from Great Britain for the investigation of plague in India it seems to have very naturally given rise to some surprise that no officer of the Indian Medical Service was nominated to serve upon that Commission. There are several medical officers of the Indian Medical Service of scientific reputation who have been trained in bacteriological work and who have made it a subject of special study, to say nothing of their knowledge of the country and the personal experience which they have acquired of the disease during the progress of the epidemic in India. It may, we think, be assumed, however, that the Government either thought it best to have a perfectly independent inquiry or that the omission was simply the result of inadvertence.

THE PLAGUE IN INDIA.

The number of victims of the plague shows a marked decline in the Bombay districts and in Bangalore but no change is reported in the Madras Presidency and the Central Provinces. The epidemic is raging in the Mysore and Hyderabad districts. Captain J. Davidson and Lieutenant J. S. Stevenson, both of the Indian Medical Service, Bengal, have been posted for plague duty in Mysore. The Chief Commissioner of Coorg has been empowered to deal with plague under the Epidemic Diseases Act.

Colonel A. Stephen, Indian Medical Service, returns to England on retirement, having tendered the resignation of his appointment as Inspector-General of Civil Hospitals, Punjab.

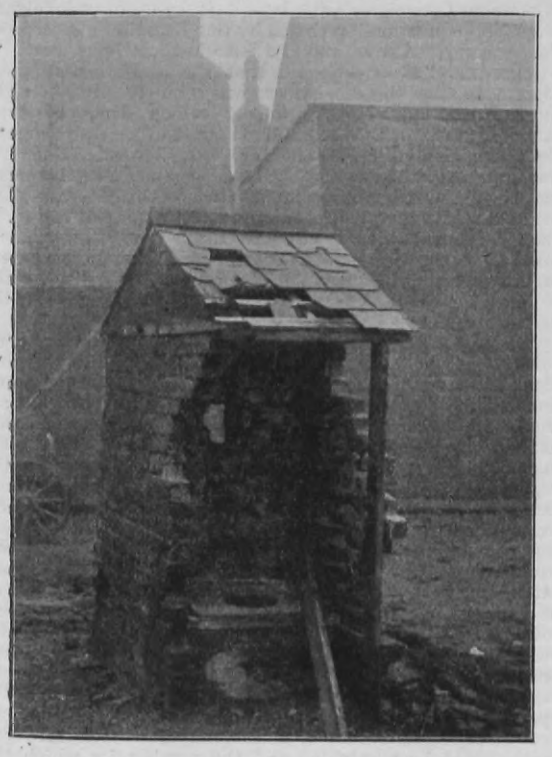
THE EPIDEMIC OF TYPHOID FEVER AT BELFAST.

SECOND YEAR.

(FROM OUR SPECIAL COMMISSIONER.)

(Concluded from p. 1739.)

ON another occasion I made my way over the Lagan to visit some of the newest streets and what are supposed to be among the best built workmen's cottages. On my way I stopped at a cheap eating-house situated in the main thoroughfare. Behind the house there was a large back-yard unpaved and with mounds of dirt and manure divided by pools of stagnant water. At one end there was a shanty with a fire burning on the floor, for there was no chimney. By the side of the fire a pig had made himself quite at home and there were plenty of poultry strutting around. Lengthways along the yard there were several stables at present only occupied by pigs, and these stables drained on to the unpaved soil. The yard was therefore full of mire and slush. A sanitary inspector had been there to see that the drain which runs near the back of the houses and at the farthest point from the stables should be repaired but he had said nothing about the paving of the yard and establishing a connexion between the drain and the stables. The rain-water from the stable roof as well as the liquid manure could not reach the drain but soaked into the soil, for the drain was some 25 ft. away from the waterspout. Eleven cartloads of manure were removed from this yard some four months ago, but it was the incoming new tenant who had to pay to have this done and now fresh accumulations are rising on all sides.



A little further on I came upon a small butcher's shop. The wall of the closet in the little back-yard had partially broken away. Only fragments of the seat remained and they were covered with soil. In the open privy behind the seat there was a pool of water with offal floating in it. The half of the yard nearest to the house was roofed over and formed a sort of shanty in which a store of meat was hung at a distance of not more than 16 ft. from this disgusting uncovered privy. There was also a big dog and its kennel here and though the yard was supposed to drain into a gully the flow was towards the privy. The flag stones used to pave the yard were loose and there was water underneath. The boards of the floor of the shop had great holes which gave a view of the low inaccessible basement beneath. Sawdust, blood, and fragments from the meat dropped down through these holes into this sort of cellar and could not be cleared away. As fermentation and decomposition proceeded the effluvium rose up through the holes and mixed with the meat exposed for sale. The inspection of this butcher's shop provided one of the strongest arguments in favour of vegetarianism which I have ever encountered.

In the —— road I entered a small cookshop where the owners were busy making tea-cakes in the back close to some pig-swill and in the midst of much dirt. The sanitary inspector had been there recently and had caused the pigsty to be removed to the furthest end

Digitized by Google

of the yard so that it might be at a distance of at least 15 ft. from the dwelling. But apparently he had not examined the closet, for I found that the pan was loose and that a part of the flush came out against the back wall. The water thus spilt does not, however, run out from under the seat and as it gets away readily it is to be presumed that it drains into the soil-pipe at some point a little below the closet-seat, where there is probably a faulty joint or a hole in the pipe. Pending such time as the sanitary inspector shall think fit to look into these matters the tea-cakes will be kneaded and baked within a few feet of this leaking closet. Of course other edibles and milk are also kept here for the customers' tea.

Adjoining the —— road there is a small street paved with round stones which are irregular and create little pools of water. The houses are so damp that bright green moss grows on the walls to a height of some 18 in. On the right-hand side some houses have been demolished and behind those which remain there is a large unpaved yard with a wooden structure in one corner which serves as a stable. Near to this stable stands the closet which I have photographed. The door, it will be seen, has disappeared long ago. The walls on both sides of the seat are in a great

measure destroyed and there is a big hole through the third wall at the back of the seat. The roof is likewise shattered. There is another seat immediately behind this perforated back wall which is scarcely less exposed to the public view than the one which is shown in the photograph. Yet this is all the accommodation afforded for the persons who live in the three houses giving on to this yard. Belfast is a town where the inhabitants profess to uphold a high standard of public morals and decency. What sense of decency and modesty is such a closet as this likely to engender? In one of the three houses which have no better provision made for them than this closet a child in my presence showed her appreciation of such accommodation by relieving herself in the middle of the back room. Her elder brother mildly suggested that she should have waited till "the gentleman was gone." Such are the manners which naturally result when no proper sanitary contrivances are available. In the yard where this dilapidated closet stands there is no dustbin, therefore the household refuse is deposited anywhere and forms mounds which stand out like islands amid the surrounding mud and slush. The wet from the stables slowly winds its way between these protuberancies till it reaches some deeper hollow and there it stagnates. Some of these pools were so foul that the water had acquired a bright green colour; and it is amidst such dirt and round this ruined closet that the boys and girls of the neighbourhood come to play and pass what should be the sunny days of their childhood.

On leaving this scene of dirt and desolation I passed by a muddy back passage with a heap of manure in it. In —— street I found that some scavengers had been extracting black mud out of the gullies, but instead of carting it away immediately and to a safe distance from the town they had spread it out over the street pavement. Here it was left to be trodden into the earth by the traffic of the street. As this black mud was spread out in thin layers and to a distance of several feet instead of being thrown up in a heap, it was evident that there was no intention of carting it away. The earth, already foul, will thus be rendered even more unwholesome. I now reached —— street. A portion of this thoroughfare consists of some of the newest and presumably the best workmen's cottages in Belfast, yet there is a back passage so full of mud and stagnant water that a pair of scavengers' waterproof boots would be required for its exploration. Evidently there are no precautions taken here and this passage has been shamefully neglected. At one end it faces an open, unbuilt, and unpaved space made up of dirty earth and pools of stagnant water. The chopped straw from the interior of some mattresses which had been destroyed was blowing about. Why were these mattresses destroyed? who had slept upon them? and was the straw they contained clean enough to be allowed to blow about and to be kicked about in the open spaces where the street-children went to play? These questions remain unanswered. I now entered one of the new cottages and at first sight it seemed a great improvement on the older houses which I had previously visited. In the back room which served as a sort of pantry there was a sink brightly enamelled which drained through the wall over the yard gully so that the disconnexion was complete. The closet in the back-yard had a good flush and at first it appeared as if no fault could be found with this cottage, but on closer examination I discovered that there had been here the same lack of supervision noticed in other parts of the town. The pan of the closet was quite loose. It had not been cemented to the trap and therefore there was nothing to prevent leakage. The earth under the seat was damp from the washings from the pan and the subsoil on which the house stood thus became contaminated when the closet pan was flushed out. There never was a better instance of the proverbial spoiling of a good ship for the want of a pennyworth of tar.

But all the houses in —— street have not got water-closets. In another house I ascertained that there had been two cases of typhoid fever — a mother and her son. At a distance of only 6 ft. from the back window there was a privy full up to the very rim of the seat. The mother had so far recovered that she was up and about but she explained to me that she was still too weak to allow the privy to be emptied. She dreaded the awful stench which would result from carrying the filth through the house, for there was no back passage for this side of the street. Also, this woman felt that she would not have the strength to clear up the mess which the scavengers would make. As her son and herself had been provided with pails during their illness she hoped that the contents of the privy were not specially dangerous. This is a good illustration of the evil effects of the absence of back passages. The privy of another house on the same side of the street was in a similar condition and here also there had been a case of typhoid fever. The inhabitants were making a sort of tea-cake close to this overflowing and uncovered privy.

—— street runs parallel with —— street and here I entered another new and nicely arranged cottage. The back-yard was well paved though not quite level. There was a clean dustbin, a good water-closet, and the pan this time was firmly fixed; but the gully in the yard over which the sink water emptied had a big hole in its side so that only a portion of the water went to the drain and the rest escaped into the subsoil through this hole. In this case, again, all that is wanted is better supervision and a handful of cement to block up a little hole. In the next house the inhabitants complained of bad odours from the back passage and in the adjoining house there was a case of typhoid fever. The patient, a youth, was recovering. Here I found that the gully in the yard did not fit properly and that the pan of the closet

Digitized by Google

was loose. No pail, I was assured, had been brought to this house; therefore the dejections from the patient had been thrown into the closet where the loose pan would allow some part of the wet to escape on to the ground under the seat. In the next house to this one there had also been fever, no less than 5 cases. A pail had been provided and the loose tile paving in the back-yard had been repaired, but the grate to drain this yard was in a bad position and a part of the water did not reach it. There was a very nasty close smell in this house.

At one end of the street there is a narrow opening forming a short passage leading to the long back passage which runs between the two streets. A board is suspended here announcing that this is the way to the —— street National School. It is true that it only leads to the back entrance and that there is a better way to the front entrance, but it is the shortest road for many of the children. One poor girl availed herself of this passage while I was looking on. It was pitiful to see her efforts to keep her feet dry and to avoid the filth. Both her arms were stretched out wide to balance herself by pressing on the walls on either side. Then she tried to step on pebbles and small stones. There was fæcal matter on all sides and a filthy stained palliasse, thrown out here no one knows by whom, though it might infect the narrow passage where so many children have to pass. Where are the scavengers? How is it that these back passages remain in such a condition? The passage running behind —— and —— street I found even in a worse condition. The doors which give access to the dust-bins were swinging or open. Straw, garbage, and vegetable refuse of all sorts were lying about, and in the midst of this filth a drunken man had fallen and was now fast asleep. Yet while these foul things fester behind the houses, in front the cottages have a smart appearance. Some are hardly more than four years old and the street is broad. Judged superficially this would be thought a healthy district. In the last house I visited there was upstairs a young woman suffering from typhoid fever. No pail had been sent for this patient and her dejections were thrown into the water-closet. On removing the seat I found that here again the pan was quite loose. The lead pipe to deliver the water for the flush was affixed to the pan by a bit of rag fastened round with some string. The pan rested loosely on the trap, nor did the trap seem to have been jointed to the soil-pipe. On the exit side of the trap there was some slight trace of clay where there should have been cement. On the other hand, the dustbin or ashpit was carefully covered over and it was evident that only a little care was needed to make this a sanitary dwelling. The sanitary inspector, I was informed, had called—he had even entered the closet and pulled the string to see if the flush worked well, but, satisfied by this perfunctory form of inspection, he had left the place without ever discovering that a bit of rag and a bit of string had been substituted for plumber's work and that the drains were not secure at the joints.

Not far from here I had noticed some digging done to lay the foundations of new dwellings. The earth looked so black and forbidding that I made my way to the end to see how ground was produced by the dumping process. Here there is a bridge over some railway lines and between the line and the last houses there is a rubbish shoot. At the foot of the rubbish there was a large pool of green water. On the opposite side of the railway the corporation carts shoot their rubbish and are thus piling up what is denominated in the neighbourhood as "Microbe Hill." It is said that the contents of privies are no longer emptied here. Perhaps this is so, but the bubbling water at the foot of these rubbish shoots smells strongly of sulphuretted hydrogen. In some places it is green, at others more like ink and it is always foul. At one "tip" now used by the Northern Railway Company I saw much straw and what seemed to have been manure. Also the heap was hot and smoking, and one wonders if houses are ever built here what sort of health the inhabitants will enjoy.

After all these investigations I must confess to being overwhelmed with a deep sense of despair. When even such easy trifles as the cementing of a closet-pan on its syphon trap are so generally neglected, though the presence of typhoid fever in the houses should have caused all such defects to be promptly detected and remedied, it is impossible to hope with much confidence that the great and sweeping measures of sanitary reform urgently needed will be efficaciously applied. Is it likely that an administration which, at any rate in the past, has displayed such crass incapacity and has been guilty of such palpable life-destroying neglect will ever be able to produce a Hercules capable of cleaning out these Augean stables? Does this not rather suggest that a higher and outside authority should interfere so that the law shall at last be enforced and that the work of efficient sanitary supervision shall be no longer neglected?

Correspondence.

"Audi alteram partem."

"THE GENERAL MEDICAL COUNCIL AND PRELIMINARY EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—In the letter of the Registrar of the General Medical Council which appears in this week's number of THE LANCET the incorrectness of the figures given in the report of the Education Committee with regard to cases of "deficiency in general education," reported by the Examining Boards of the "Navy, Army, and Indian Medical Services," is admitted, and it is explained that the limitation of these reports to the three services was due to an oversight in the drafting of the report which has, however, already been issued to the public in the half-yearly volume of the Council's minutes, is printed in THE LANCET of Dec. 3rd, has been made the subject of general comment in the press, and has been officially communicated to this College. The oversight is, to say the least, unfortunate, as the report, in the form in which it was presented to the Council, was calculated to convey a most erroneous impression as to the extent of the alleged "deficiency in general education" attaching to persons who had registered as medical students on the certificates of this College.

It is now stated that the figures given in the report comprise the whole of the cases reported by the various Examining Boards, "including those for the Navy, Army, and Indian Medical Services," and that out of these 14 are those of candidates who had passed their preliminary examination at the College of Preceptors. With regard to the accuracy or otherwise of the figures given in the table in the registrar's letter, it may be sufficient to say that the total number of cases reported is, after the most careful examination of the published minutes, found to be, as set out in the accompanying table, not 58 but 84, or, exclusive of cases not traced, 65. The number of the cases attributed to the College of Preceptors is apparently arrived at by including some cases in which under the old "piecemeal" regulation of the General Medical Council candidates were registered on certificates obtained from more than one examining body. As it would be impossible to say whether the subject of "English," in which the spelling test is usually included, was passed at one or the other examination, it seems only fair that all such cases should be eliminated and the number for which the College of Preceptors may be held to be responsible would then be reduced to 11—,11 cases in seven years out of a total of 2133 candidates who during that period have come on the Medical Students' Register by means of College of Preceptors' certificates. The proportion of cases traced to the College is therefore represented by the fraction $\frac{11}{193}$, or about ½ per cent. The total number of medical students registered during the past seven years amounts to 12,526. The average of traced cases of deficiency would therefore be 1 in 193, or ½ per cent., the same proportion as that attributable to the College of Preceptors. But if only the number of those who have qualified on one or other of the *junior* or *preliminary* examinations in the United Kingdom be considered the proportion would be 65 out of 8467, or 1 in 130, or about ¾ per cent.

The proportion of reported cases of "deficiency in general education" amongst candidates who have qualified during the same period on certificates of the Irish Intermediate Education Board is represented by the fraction $\frac{3}{100}$, or nearly 2 per cent., which is a somewhat different ratio from $\frac{11}{193}$. Nevertheless this examination is retained on the list, as are also the public entrance and other pre-graduate examinations of Trinity College, Dublin, with a proportion taken together of $\frac{3}{100}$, or nearly 3 per cent. The mere statement of these

Digitized by Google

facts reduces the whole matter to its true proportions and exhibits in the clearest light the triviality of the charge that has been brought against the College of Preceptors' examination and made so prominent a feature in the report drafted, as was stated by the chairman of the committee, by Dr. MacAlister. I am, Sirs, yours faithfully,

H. W. EVE,
Dean of the College of Preceptors.

Bloomsbury-square, W.C., Dec. 27th, 1898.

"THE SEAMEN'S HOSPITAL SOCIETY AND ITS VISITING STAFF."

To the Editors of THE LANCET.

SIRS,—The letter in your issue of last week, signed John Curnow, M.D., F.R.C.P., John Anderson, M.D., F.R.C.P., G. R. Turner, F.R.C.S., might lead readers to infer that in various publications I had deliberately assumed a title to which I had no claim, that knowing that this description was untrue I had designated myself "Physician to the Seamen's Hospital, Greenwich." In self-defence I am constrained to ask you to allow me space to make the following statement.

In 1892 I was appointed a physician to the Seamen's Hospital Society. My duties, I was informed, were sole charge of the medical cases in the society's Branch Hospital, Albert Docks; to visit convalescents at the *Dreadnought* Hospital, Greenwich, when transferred there from the Branch Hospital; to take part in the meetings of the society's honorary visiting staff. In discharge of these duties I visited the Seamen's Hospital, Albert Docks, twice a week, and the Seamen's Hospital, Greenwich (*Dreadnought*), once a week, and attended most, if not all, of the meetings of the medical staff to which I was summoned. At the time of my election I was not informed that my office carried with it any particular title; but as I performed all the duties of a hospital physician at both of the Seamen's Hospitals I naturally inferred that I was a physician to both of these hospitals and that I had a perfect right to designate myself as such. Accordingly, and in conformity with medical custom, I called myself, or was called in various publications, sometimes "Physician to the Seamen's Hospital, Greenwich," sometimes "Physician to the Seamen's Hospital, Greenwich, and Seamen's Hospital, Albert Docks."

Some three years ago I was pained and surprised to be informed by the secretary of the Seamen's Hospital Society that my colleagues (as I regarded them) at the *Dreadnought* (Seamen's Hospital, Greenwich) had collectively and officially represented to him that I had assumed a title to which I had no right and that he had been asked officially to request that I should discontinue the practice. If I am not mistaken (unfortunately I have destroyed the correspondence) I was requested to write to the medical press and publicly intimate that I was not a physician to the Seamen's Hospital, Greenwich, and that I had no right so to describe myself. I protested. After some correspondence, in the course of which I intimated that I considered that my colleagues might have spoken to me privately if they thought I was in error or considered themselves aggrieved, I expressed regret if I had unwittingly arrogated to myself a title to which I had no claim. In consequence of the want of consideration shown me by my colleagues at the *Dreadnought* I have ceased to visit there, feeling that my seniors did not care to be associated with me, and myself not caring to be associated with those who, I considered, had treated me with scant courtesy, not to say fairness or friendliness.

At the time of the correspondence referred to I did consider, as I still consider, that I had a perfect right—in fact as much right as either Dr. Curnow or Dr. Anderson had—to designate myself "Physician to the Seamen's Hospital, Greenwich." I regret now that, shrinking from a petty squabble and for the sake of peace, I gave way on what at the time seemed to me to be a most trivial matter.

I am, Sirs, yours faithfully,

PATRICK MANSON.

Queen Anne-street, Cavendish-square, Dec. 28th, 1898.

"CLEANSING THE LESSER PERITONEAL CAVITY."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to reply to Mr. Furner's letter in your issue of Dec. 24th? My "note" was headed "Perforated Gastric Ulcer" and dealt for the most part with two points other than that of cleansing the lesser peritoneal cavity. The facts are very simple. Some time ago, as my "note" says, I read a case of death from the giving way of a second ulcer opposite to one on the anterior wall which had perforated and which I had closed. *At that time* I pointed out that it would be well to adopt a practice of examining the posterior wall to prevent this disaster. *Mr. Furner, when reading his paper, spoke of my case and of my suggestion that the posterior wall should be examined.* I did not, when advocating this, make any allusion to cleansing the cavity or the prevention thereby of the formation of an abscess. What I claim to have advised (a simple but not unimportant custom) no one who heard me read my case will deny that I did advise. Again anyone fairly reading my "note" in your paper will see that as between Mr. Furner and myself I give him full credit for drawing attention to the need of cleansing the lesser peritoneal cavity and the good which would arise from doing it as a matter of routine.

I had a perfect right to draw the attention of surgeons to two points I thought my experience had shown me were important and not generally recognised. Had I known Mr. Furner was about to publish his paper I would certainly have left out any allusion to his point of cleansing the cavity. I must add, however, that I am not conscious of having treated him unfairly by accident even, certainly not by design. I am, Sirs, yours faithfully,

Brighton, Dec. 26th, 1898. T. JENNER VERRALL.

"FIRES IN LUNATIC ASYLUMS."

To the Editors of THE LANCET.

SIRS,—Your note on the recent fire at this house scarcely does justice to the staff.

The patient whose life was lost was not merely aroused

Digitized by Google

but was brought downstairs into a place of perfect safety, being the very first person in the house to be rescued. He met his death by going back to the scene of the fire to get his belongings. It was not on the arrival of the firemen that the unfortunate man was first missed and searched for. He was missed a quarter of an hour before the firemen arrived and every room had been searched and every bed had been felt before the firemen arrived at the house. The closet in which the deceased was eventually found had been searched after he was missed and before the firemen arrived and he was not then in it. The firemen are deserving of the highest praise for the manner in which they performed their duties; but, in giving them the credit which is justly their due it is only fair to add that the house staff was equally efficient in circumstances that to them were much more trying.

I am, Sirs, yours faithfully,

Catford, S.E., Dec. 24th, 1898. CHARLES MERCIER.

A SUGGESTED EXPLANATION OF CERTAIN PECULIAR CARDIAC PHYSICAL SIGNS IN PHTHISIS.

To the Editors of THE LANCET.

SIRS,—Attention has recently been called [1] to the presence of cardiac impulse and sounds on the right side of the chest although on post-mortem examination the heart was found in its normal position. In the cases referred to there existed cavity formation at the upper part of the right lung with consolidation of the lower lobes. At first sight it seems difficult to account for the peculiar phenomena observed, but a few remarks will, I hope, make the reason quite clear. It is a well-known fact, demonstrated by many authorities, that during respiration we often find cardio-pneumatic sounds produced which simulate closely organic cardiac murmurs, and indeed are often mistaken for these. They may be heard either in cardiac systole or in cardiac diastole and at times during both movements of the heart. Where there exists a cavity in the lung the sounds produced in that cavity may give rise to similar cardio-pneumatic murmurs. In the cases already referred to the cavities present were situated close to the cardiac organ and, moreover, had, so to speak, a bridge of consolidated lung connecting the heart with the cavity. In this way the cardio-pneumatic murmurs were conducted downwards from the cavity to the intercostal space on the right side over which they were audible. In a similar manner the impact of the heart was rendered visible and palpable on the right side of the chest by this combination of cavity and consolidation. It would appear that the presence of consolidated lung cannot of itself cause this conveyance of cardiac impulse else it would be observed in cases of lobar pneumonia; there must also be cavity formation present above the consolidated area. It is the presence of a cavity that is one of the *sine quâ nons* of cardio-pneumatic murmurs in phthisis and it is likewise the essential in the conveyance of cardiac movement to the right side of the chest. During the stage of cavity formation in phthisis I have frequently remarked the presence of these so-called cardio-pneumatic sounds not only in the region of the cavity but at an entirely opposite part of the chest and have always observed that in such cases there was a well-defined bridge of consolidated lung substance existing between the cavity and the area other than that of the cavity itself over which these murmurs were audible. There can be no doubt whatever that the cardiac impulse is conveyed in a similar manner, the transmission being due to the peculiar combination of cavity and consolidation in direct proximity to the heart. Cases of this kind are by no means rare and a clear understanding of the conditions present is most essential to the practitioner. I am quite convinced from personal observations that such misleading phenomena as I have been considering never occur unless we have cavity formation co-existent with consolidation in the same lung. If this fact is borne in mind I think no further difficulty will be experienced in accounting for what must always prove to be interesting, as they are striking, phenomena.

I am, Sirs, yours faithfully,

JAMES BURNET, M.A. Edin., M.B. Edin.

Cumin-place, Edinburgh, Dec. 12th, 1898.

ERRATUM.—In a letter signed "H. E. G." which appeared in our issue of Dec. 24th upon "Diphtheria Antitoxin in Private Practice," p. 1733, the price quoted for 2000 units of serum was wrongly printed as 17*s.* 6*d.* It should have been 17*s.* 3*d.*

[1] THE LANCET, Nov. 19th, 1898, p. 1323; and Dec. 10th, 1898, p. 1548.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Bacterial Treatment of Manchester Sewage.

A PRELIMINARY report, signed by the three experts appointed some months ago to consider and report on the best methods of treating the Manchester sewage, has been addressed to the Rivers Committee of the corporation. It is a very satisfactory one to those who have been looking with hope to the bacterial treatment for solving the difficult problem of sewage disposal. The report is too long for transcription, but Messrs. Baldwin Latham, Percy F. Frankland, and W. H. Perkin, jun., say, "without hesitation that from the results obtained with the double contact beds constructed according to our instructions at Davyhulme by your city surveyor and the experiments carried on by us which have been directed to the treatment and purification of settled and crude sewage without the use of any chemicals we are of opinion that the bacteriological system, notwithstanding the particular nature of the Manchester sewage, will purify that sewage and will yield an effluent which will comply with all the requirements of the Mersey and Irwell Joint Committee and which when discharged into the Ship Canal will, in our judgment, be the means of greatly improving the waters of the latter." One of the strongest *a priori* points which the advocates of the culvert to the sea or other modes of dealing with the sewage of Manchester insisted on was that the chemical refuse which was discharged into the sewers would put a stop to bacterial action. In an appendix to the report Mr. Gilbert J. Fowler, the chemist, says: "In no case has the presence of manufacturing refuse shown a marked tendency to render the purification less effective." Any mineral acids seem to be neutralised by the alkaline carbonates, soaps, &c., for "in no case has the sewage been found to be acid with mineral acid." The Local Government Board is to hold an inquiry on Jan. 12th, 1899, into the working of the system, when the experts are expected to give evidence. It is proposed to limit the inquiry to the main principles determining the treatment of the sewage at Davyhulme, reserving details as to plans and estimates for a later inquiry.

Bromoform Poisoning.

An inquest was held on Dec. 22nd at Lancaster concerning the death of a little girl, five years old, the daughter of the infirmary porter. It seems that 36 minims of bromoform were put in a mixture made up with mucilage and water and the child died after the last dose had been taken. The theory was that the whole of the bromoform had been left at the bottom of the bottle and taken in the last dose from its not having been well shaken as directed. The report is rather meagre and as this is said to be the first recorded case of bromoform poisoning it would be well if a fuller account were given.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

THE following are the numbers of students who attended the several courses of lectures in the University of Edinburgh during the year 1897-98: botany, 174; zoology, 205; chemistry, 241; anatomy, 228; physiology, 436; materia medica, 217; pathology, 180; medical jurisprudence, 203; medicine, 252; surgery, 241; midwifery, 113; mental diseases, 166; and opthalmology, 117.

The Inebriates Act, 1898.

This important statute will come into operation on Jan. 1st, 1899. Meantime a committee to frame regulations for the proposed inebriate reformatories in Scotland and generally to advise the Secretary for Scotland as to the methods of working the Act is sitting. At first there was no medical man on that committee. The Royal Colleges of Physicians and Surgeons of Edinburgh and the Glasgow Faculty of Physicians and Surgeons pointed out this omission to the Lord Advocate, who at once requested the presidents of those

Digitized by Google

corporations to name a medical man who "would command the confidence of the profession." They nominated Dr. Clouston, who accordingly has been added to the committee.

Glasgow University.

The George A. Clark Scholarship of £170 for four years has been awarded to Mr. Hugh R. Buchanan, M.A.; the senior Arnott prize for an examination in physiological physics to Mr. James M'Pherson, M.A.; and the junior Arnott prize for an examination in general physics to Mr. Alex. Macintyre. At a recent meeting of one of the students' clubs Professor Bradley, in replying to the toast of "Alma Mater," alluded to the work of the University Commission and expressed the opinion that the results would in all respects be beneficial, even though in some respects the necessary alterations produced temporary difficulties. The diminution in the number of students, largely consequent upon a more stringent preliminary examination, was in one sense unfortunate, but compensation might be expected in the shape of more efficient secondary education throughout the country and the cessation of junior classes in the University would leave more energy free for the prosecution of the higher ranges of scholarship. The new arrangements by which the emoluments of the professors are independent of the number of students attending their classes Professor Bradley regarded with unqualified approval. He advocated a scheme by which students on coming up to the University could receive directions in reference to the curriculum they should pursue. Hitherto the public professional criticisms on the University Commissioners have been rather of an adverse order; it is refreshing to hear a more optimistic note from one of the younger members of the senatus. To the general regret Professor Coats is again laid aside by illness; his senior assistant, Dr. L. R. Sutherland, has also been somewhat seriously ill. The charge of the pathological department has been committed to the care of Dr. A. R. Ferguson.

The Royal Infirmary, Aberdeen.

The number of in-patients admitted to the Royal Infirmary during the year is given as 2363, and 208 were left under treatment on Dec. 19th. There were also 2116 casualty cases of a minor kind and 3382 out-patients. It is stated that there will be a deficit in the funds for the year of upwards of £1200.

Dec. 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Christmas at the Dublin Hospitals.

THE Royal Hospital Infirmary was visited by Field-Marshal Lord Roberts, V.C., accompanied by the Hon. Aileen Roberts, Lieutenant the Hon. F. H. S. Roberts, A.D.C., the Adjutant, Captain Fielding, and the Staff Surgeon, Dr. Carte. His lordship presented the old warriors with gifts of wine, fruit, and tobacco. At the Children's Hospital, Temple-street, Her Excellency the Countess Cadogan will preside at the Christmas tree *fête* which will take place on Dec. 28th.

Filled-up Dumping Ground.

A very important case was tried at the Belfast Recorder's Court on Dec. 22nd in which a man brought an action against another man to recover £50 for alleged damages caused by a nuisance which resulted in a noxious smell owing to filth having accumulated on the defendant's lands and for wrongfully allowing polluted water to flow into the lands of the plaintiff. It would appear that the plaintiff lives in a cottage near the River Lagan and that about one year ago the defendant caused to be deposited near his house a material with a most offensive smell which a sanitary engineer who was examined said was "filling-up" matter composed of ashpit refuse and road scrapings. He was told it was done by the corporation. Dr. Whitaker, medical officer of health of Belfast, said the main damage was that the view of the River Lagan from plaintiff's house was interfered with. The plaintiff's case was that the matter used as "filling up" substance was hurtful to his family's health and a medical man swore that he had treated plaintiff's daughter for typhoid fever in the month of July. The jury found for the plaintiff and awarded the full amount claimed—£50. I trust the result of this case will put an end for ever to this abominable practice, so prevalent in Belfast, of "dumping" down stuff (often from ashpits, &c.) in various parts of the city. The case will in the future in Belfast be regarded as a test one.

Dec. 27th.

Obituary.

ALFREDO ANTUNES KANTHACK, M.A. CANTAB., M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF CAMBRIDGE.

ON Dec. 21st there passed away the foremost of the younger generation of pathologists in the person of the Professor of Pathology in the University of Cambridge. Alfredo Antunes Kanthack was born in Brazil in 1863, the second son of Emilio Kanthack of Para, at one time Her Majesty's Consul in that town. He was educated in Germany, chiefly at Hamburg and Luneburg, during his early years, but afterwards he studied at University College, Liverpool, St. Bartholomew's Hospital, St. John's College, Cambridge, and Berlin. He became a Member of the Royal College of Surgeons of England in 1887 and a Fellow in 1888, a Member of the Royal College of Physicians of London in 1892 and a Fellow in 1897.

After taking the Fellowship of the Royal College of Surgeons and completing his M.B. and B.S. at the University of London he went almost at once to Berlin. Here he began his first real work in pathology. A pupil of Virchow, of Koch, and of Krause he speedily attracted the attention of his teachers as an ardent worker, both clinically and in the laboratory. A paper on the Histology of the Larynx, published in Virchow's Archives, established his reputation as an original observer and a controversialist of skill. Using to the full his enormous capacity for work he laid here the foundation of his all-round knowledge of pathology which was so striking a feature of his later years. He made many friendships and only a few days before his last illness he was the companion of Professor Virchow in many of the journeys which the latter made during his recent stay in this country. In the year 1890 he went as a Commissioner appointed by the National Leprosy Fund to India with the late Dr. Beaven Rake and Dr. Buckmaster to investigate the question of leprosy in that country. Some of the conclusions embodied in the report did not find favour with certain of the members of a special committee appointed to consider it, but it received the approval of the scientific members of the executive committee who accepted the conclusions while bearing testimony to the great care and ability with which the inquiry had been conducted.

On his return from India in 1891 he was elected John Lucas Walker Student at Cambridge and he published several papers as the result of his year's work. Many of the papers dealt with the question of immunity and, whilst denying the claims of Metchnikoff, at that time almost universally allowed, that the phenomena of phagocytosis completely explained the processes of immunity, he guarded himself from accepting the extreme claims of the supporters of the humoral theorists. The most important of these papers, published conjointly with Mr. Hardy, appears in the Proceedings of the Royal Society, vol. lii. At this time was published his paper on Madura Disease in which he demonstrated the parasitic nature of the affection and its close resemblance, if not identity, with actinomycosis. After a year passed in Liverpool he went to St. Bartholomew's Hospital in 1893, and while there, notwithstanding the claims made on his time by the work of his post—that of lecturer on pathology—he was able to contribute many valuable papers, mostly in connexion with his daily work and on a great variety of subjects to the medical journals and the publications of the various societies. On leaving St. Bartholomew's in 1897 to succeed Professor Roy at Cambridge it seemed possible that he would gain the leisure necessary for a larger measure of work of his own.

During the autumn of this year, 1898, came the report on the inquiry into the tsetse fly disease which he was conducting with the aid of Dr. Durham and Mr. Blandford. The failure of all attempts to find a cure for this South African scourge is disappointing, but the report contains much that is of value concerning points in doubt or of error with regard to

Digitized by Google

infectivity of various animals. His last work, published with Dr. St. B. Sladen a few days before his death, was concerned with the infectivity of milk as supplied to the consumer in regard to tuberculosis. His acquaintance with the literature of his subject in nearly all its branches was very remarkable and this with his wide practical experience made him an authority alike in general pathology, pathological histology, and bacteriology. In addition a fine critical sense and the extraordinary influence which he had over his pupils made him almost an ideal teacher, especially of beginners in research. An assured position he already held and his work seemed to promise great things in the future, but his loss to pathology in England is to be especially deplored for had he been spared he would by his example and guidance, by his energy and enthusiasm in the post which he held, have had a very large influence on its progress. His travels abroad had brought him in contact with many of the best workers on the continent and in India and he had many friends in America. His foreign correspondence was very large—much of it created by his own writings. Abroad as well as in England many will grieve at the loss of a friend and counsellor removed from our midst at so early an age.

His published works include "Leprosy in India," which was the report of the Leprosy Commission published in 1892 conjointly with his fellow Commissioners, "A Manual of Practical Morbid Anatomy," 1894, and "A Handbook of Practical Bacteriology," 1895. Besides these he wrote many most valuable communications to the scientific journals, especially to the *Journal of Pathology* and the Proceedings of the Royal Society. His Jacksonian Prize Essay was won in 1895 and bore for motto a drawing of some bacilli with the following words:

> "What are these
> So withered and so wild in their attire,
> That look not like the inhabitants o' the earth
> And yet are on't?"

It is scarcely necessary to add that the essay dealt with the subject of Tetanus.

Professor Kanthack was widely read—a good linguist and a man of thoroughly cultured mind, with a singular charm of manner. Dowered as he was with so many gifts his place will indeed be hard to fill. The funeral—which took place on Dec 24th at Cambridge, the first part of the service being sung in the chapel of King's College, of which society he was recently elected a fellow—was attended by a large number of friends and relations, and representatives of the University and the various scientific and learned bodies of which the deceased was a member.

WILLIAM MUNK, M.D. LEYDEN, F.R.C.P. LOND.,

HARVEIAN LIBRARIAN TO THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

BY the death of Dr. William Munk who passed away at his residence, Finsbury-square, on Dec. 26th the medical profession loses one whom it can ill afford to spare. In addition to being a sound and capable physician Dr. Munk was a scholar, an antiquarian, and a writer of fluent and stylish prose. As librarian to the Royal College of Physicians of London he exhibited all those qualities which are so necessary for the post but which it is almost impossible to acquire unless the possessor of them is so gifted by nature.

Dr. Munk was born in 1816. He received his medical education at University College, London, and at the University of Leyden where he graduated M.D. in 1837. He became a member of the Royal College of Physicians of London in 1844 and a Fellow of the same body in 1854, being elected Harveian Librarian in 1857. He was senior censor of the College in 1882 and vice-president in 1888–1889. His first medical appointment was that of demonstrator of morbid anatomy to the medical school of St. Thomas's Hospital. For many years he was physician to the Royal Infirmary for Asthma, Consumption, and Diseases of the Chest and at the time of his death was consulting physician to the Royal Hospital for Incurables. He held the post of consulting physician to the Small-pox and Vaccination Hospital for some forty years, and was one of the first authorities upon small-pox. Of his literary labours the most important was without doubt the extremely carefully edited volume entitled "The Roll of the Royal College of Physicians," of which the first edition appeared in 1861 and the second, revised and enlarged, in 1878. The first edition was in two volumes and the second in three. The third edition comprised the period between 1518 and 1825, at which latter date the Royal College of Physicians of London was removed from Warwick-lane to its present site in Pall-mall. The work consists of a series of short biographies of the practitioners included in the "Roll" and its tenor may be judged from an extract from the preface to the third edition. After apologising for the necessarily monotonous character of the work Dr. Munk proceeds: "The more successful a physician is, the more he is engaged in the best duties of his office, the less is there to meet observation or to court publicity, and the less material, therefore, for biography. 'The physician's part,' says Johnson, 'lies hid in domestic privacy, and silent duties and silent excellencies are soon forgotten.'" Other works from his pen were "Euthanasia, or Medical Treatment in Aid of an Easy Natural Death," which appeared in 1887, and "The Life of Sir Henry Halford, Bart., M.D.," which appeared in 1895. In 1884 he edited "The Gold-headed Cane." This last little book was originally written by Dr. Macmichael, the registrar of the College from 1824 to 1829, and was cast in the form of an autobiography related by "The Gold-headed Cane" preserved in the library of the College, which was carried successively by Radcliffe, Mead, Askew Pitcairn, and Baillie. Dr. Munk, in editing the original edition, added particulars dealing with Halford, Paris, and Mayo, bringing the autobiography down to 1862. "Euthanasia" was an earnest and learned plea for the recognition of the duty which physicians owe to their patients not to end life but to render its passing in hopeless cases more easy. The book was the foundation of a leading article in THE LANCET of Dec. 10th, 1887. In the early part of this year the Fellows of the Royal College of Physicians, as a mark of their gratitude for the forty years' labour of Dr. Munk as librarian, subscribed for his portrait to be painted. The commission was entrusted to the Hon. John Collier and the picture which was completed in July now hangs in the dining room of the College. The primary cause of the death of Dr. Munk was glycosuria.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Fellows of the College and have received their diplomas:—

Claud Alley Worth, L.R.C.P. Lond., St. Bartholomew's Hospital; diploma of Membership dated May 11th, 1893.
Arthur Godfrey Ince, L.R.C.P. Lond., Charing-cross Hospital; May 10th, 1894.
George Herbert Sowry, M.B., B.S. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital; May 9th, 1895.
Nathaniel Bishop Harmar, M.B. Cantab., L.R.C.P. Lond., Cambridge University and Middlesex Hospital; July 29th, 1895.
Hugh Thomas Symes Bell, L.R.C.P. Lond., Guy's Hospital; Feb. 13th, 1896.
Arthur William Ormond, L.R.C.P. Lond., Guy's Hospital; August 4th, 1896.
Alfred Walter Sikes, B.Sc., L.R.C.P. Lond., St. Thomas's Hospital; August 4th, 1896.
William Ilbert Hancock, L.R.C.P. Lond., Guy's Hospital; Nov. 12th, 1896.
William Stuart-Low, L.R.C.P. Edin., L.F.P.S. Glasg., Edinburgh, St. Thomas's and St. Bartholomew's Hospitals; May 13th, 1897.
James Atkinson Bonnin, M.B., Ch.B. Adel., L.R.C.P. Lond., Adelaide University and London Hospital; July 29th, 1897.

Four other gentlemen passed the examination, but have not yet attained the legal age, and will receive their diplomas at future dates. Twenty gentlemen were referred for six months and one gentleman for twelve months.

UNIVERSITY OF CAMBRIDGE.—The following candidates were successful at the examinations for medical and surgical degrees Michaelmas term:—

THIRD EXAMINATION.

Part I., Surgery and Midwifery.—R. Ainsworth, B.A., Pembroke; H. F. Bassano, B.A., Trinity; E. H. Cornaby, B.A., non-collegiate; E. Cox, B.A., Caius; S. W. Curl, B.A., Downing; W. S. Darby, B.A., Trinity; N. Devereux, M.A., H. Selwyn; A. T. Fraser, B.A., Caius; J. H. P. Fraser, Jesus; A. C. Fry, Pembroke; H. A. Gaitskell, M.A., Clare; F. A. Godson, B.A., St. John's; J. Cutch, M.A., Christ's; G. E. Harthan, B.A., Jesus; H. M. Harwood, B.A., Trinity; C. L. Hawkins, B.A., Emmanuel; N. Heard, B.A., Down; J. E. Helm, B.A., Magdalene; M. Horne, B.A., Trinity; R. J. Horton-Smith, M.A., and O. Inchley, B.A., St. John's; G. F. Lobb, B.A., and N. J. McCaskie, B.A., Caius; A. E. Martin, B.A., Down; J. C. Matthews, B.A., St. John's; H. R. Mayo, B.A., Caius; T. A. Mayo, B.A., Clare; W. T. Mullings, B.A., Christ's; J. P. L. Mummery, B.A., Caius; F. J. Nicholls, B.A.

Digitized by Google

St. John's; G. E. Orme, B.A., Caius; F. A. Rose, B.A., St. John's; R. N. Salaman, B.A., Trinity Hall; F. Shufflebotham, B.A., Trinity; J. F. Skrimshire, St. John's; E. Talbot, B.A., Trinity; R. S. Trevor, M.A., Clare; A. N. Walker, B.A., Queens', and W. B. Winton, B.A., Clare.

Part II., Medicine, &c.—J. L. Allen, B.A., King's; C. H. Barnes, B.A., Christ's; P. F. Barton, B.A., and J. A. H. Brincker, B.A., St. John's; A. E. Carsberg, B.A., Caius; A. W. Daniel, B.A., Emmanuel; S. E. Denyer, M.A., Queens'; W. Eardley, M.A., St. John's; E. E. Glynn, B.A., Clare; W. D. Harmer, B.A., King's; G. E. Harthan, B.A., Jesus; H. M. Hart-Smith, B.A., and J. H. F. Jerrard, B.A., Caius; M. B. Johnson, B.A., Trinity Hall; A. C. Jordan, B.A., Sidney-Sussex; G. S. Keeling, B.A., Caius; T. W. Letchworth, B.A., Emmanuel; F. J. Lidderdale, Trinity; A. F. MacCallan, B.A., Christ's; P. L. Moore, B.A., and B. A. Percival, B.A., St. John's; S. P. Pollard, B.A., Caius; C. Powell, B.A., Emmanuel; C. Reissmann, B.A., St. John's; E. P. Sewell, B.A., Pembroke; C. C. Simson, M.A., Trinity; P. T. Sutcliffe, B.A., Emmanuel; E. C. Taylor, B.A., St. John's; H. C. Thorp, B.A., Emmanuel; I. Ll. Tuckett, M.A., Trinity; A. N. Walker, B.A., Queens'; A. M. Ware, B.A., Pembroke; W. K. Wills, M.A., St. John's; R. J. Willson, B.A., Emmanuel; and A. G. Wilson, B.A., Caius.

The Special Board for Medicine have elected Dr. Allbutt, Regius Professor of Medicine, to be their representative on the General Board of Studies until Dec. 31st, 1902. The General Board of Studies have re-appointed Dr. Hill, Master of Downing College, University Lecturer in Advanced Human Anatomy till Michaelmas, 1903, and the appointment has been confirmed by the Special Board for Medicine.

THE QUEEN has conferred the Hon. Associateship of the Order of St. John of Jerusalem on Dr. G. T. Cattell.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—The committee of the South Devon and East Cornwall Hospital has acknowledged the receipt of £560 from the Hospital Saturday Fund.

RAILWAY ACCIDENT TO A MEDICAL MAN.—Mr. A. Jeffreys of Abercanaid who was injured so seriously at Abercynon Station has had both arms amputated in the Cardiff Infirmary and is progressing favourably.

FOOTBALL CASUALTY.—A verdict of "Accidental death" was returned at an inquest held in Aberdare upon a football player, aged thirty years, who was injured in a football match played between Aberdare and Porth. Deceased sustained a compound fracture of the left leg and tetanus followed.

COCAINE POISONING.—An inquest has been held at Trefusis, Cornwall, upon the body of a man who was found dead in bed on Dec. 19th. Evidence showed that the deceased was in the habit of taking cocaine. Dr. Knuthsen stated that death was due to an overdose of cocaine and a verdict to that effect was returned.

THE VACCINATION ACT.—At the meeting of the Chipping Sodbury Board of Guardians held on Dec. 21st, under the presidency of Sir G. Codrington, Bart., a resolution was passed with only two dissentients to petition the Houses of Parliament to repeal the Vaccination Act of 1898 without delay. The Duke of Beaufort spoke strongly in favour of the resolution, giving some of his military experiences which plainly showed the efficiency of vaccination, and added that unless something was done to re-establish compulsory vaccination they would have a plague of small pox all over the country.—At a meeting of the Torrington Board of Guardians held on Dec. 17th a resolution was passed condemning the new Vaccination Act.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BAIN, J. W. D., M.R.C.S., has been appointed a Public Vaccinator for South Australia.

BENINGTON, R. C., M.D., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed a Health Officer for Claremont, Western Australia.

BROWN, WILLIAM, M.D., C.M. Glasg., has been appointed Public Vaccinator for the Fishponds District by the Bristol Board of Guardians.

BURD, CYRIL P., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon for the Salop Infirmary, Shrewbury.

CARLEW, T. W., M.D. Canada, has been appointed a Clinical Assistant for the Chelsea Hospital for Women, Fulham-road, London, S.W.

COLE, J. W. E., L.R.C.P. Lond., M.R.C.S., has been appointed an Assistant Medical Officer for the Infirmary of the City of London Union.

DAVIES, RICHARD, M.D., Ch.M. Edin., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of the Cheltenham Union Workhouse, vice S. T. Pruen, resigned.

DICKINSON, J., M.B. Lond., has been appointed a Health Officer for Bridgetown, Western Australia.

DOUGLAS, C. E., M.D. Edin., has been re-appointed Medical Officer by the Cupar Town Council.

FLOOD, PHILIP, L.R.C.S., L.R.C.P. Irel., has been appointed Public Vaccinator for the St. Philip and Jacob Registration District by the Bristol Board of Guardians.

GARD, HENRY, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Northern District by the Devonport Board of Guardians.

GENT, W. C., L.R.C.P. & S. Edin., has been appointed Public Vaccinator for the Knowle Registration District by the Bristol Board of Guardians.

GIBSON, THOMAS, M.B., Ch.M. Edin., has been appointed a Public Vaccinator for South Australia.

HALFORD, A. C. F., M.B., Ch.B. Melb., has been appointed a Resident Surgeon for the Claremont Hospital, Queensland.

HARKNESS, E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Public Vaccinator for Yea, Victoria, Australia, vice J. F. Matthews.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, **AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.**

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1898 which is completed with the issue of to-day will be given in the next number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1898 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.* carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

THE LANCET for the current half-year, July to December, consists of *twenty-seven* numbers, instead of the usual twenty-six. No additional charge for the extra number has been made to those Subscribers who obtain their copies *direct* from the Offices of THE LANCET, 423, Strand, W.C., and whose subscriptions, either quarterly, half-yearly, or yearly, are contemporaneous with the usual quarterly divisions of the year.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

THE WAG'S CONSCIENTIOUS OBJECTION.

CONSCIENTIOUS objectors have been rather in evidence recently, but a young man who applied this week to Mr. Sheil basing his claim for immunity for his child on the alleged fact that he had lost two children from diphtheria following vaccination certainly supplied the most startling example of ignorance. Mr. Sheil refused to accept the objection on this plea as a conscientious one, and it is difficult to see how a man can claim that his conscience has proved him to believe in what five minutes of inquiry would have proved false.

DEATH FROM PTOMAINE POISONING.

MR. G. E. HILLEARY held an inquiry on Tuesday night last at the Canning Town Coroner's Court into the circumstances attending the death of a little girl, aged three and a half years, who was taken ill shortly after eating some tinned beef for dinner. No other member of the family felt any ill effects after partaking of the beef and the coroner elicited that the deceased had eaten some painted sweets. Mr. W. W. Farnfield, resident medical officer of St. Mary's Hospital, Plaistow, said the cause of death was ptomaine poisoning, the result most probably of eating some unwholesome articles of diet, it being his opinion that the tinned beef was the cause. The jury returned a verdict of "Death from misadventure," and the question of the composition of the sweets appears not to have been gone into.

PLAGUE IN MALEGAON.

ONE of the most interesting pictures of work in a plague-stricken community appears in a place which at first sight would seem most unlikely for this kind of literature—namely, the pages of a public school magazine—*The Wykehamist* for Dec. 20th. "Year by year," says Kipling, "England sends out fresh drafts for the first fighting line which is officially called the Indian Civil Service. These die or kill themselves by overwork, or are worried to death or broken in health and hope, in order that the land may be protected from death and sickness, famine and war, and may eventually become capable of standing alone. It will never stand alone, but the idea is a pretty one and men are willing to die for it." The article referred to is written by one of this fighting line in question, an old Wykehamist and is a plain unvarnished record of hard work. The population of Malegaon is mainly composed of Mussulman weavers who wander over the country-side selling their work and it was by the agency of one of their customers from Bombay who eluded the cordon of guards that plague was introduced. The old Wykehamist set to work with the help of one native doctor who, we are sorry to say, was a venal person. A few days after the outbreak he appeared in a new suit of shiny black broadcloth which was considered suspicious. Suspicion soon crystallised into certainty when he was caught letting off the family of a rich man from going to hospital although there was a case of plague. In a week the native doctor was dead. There was no hospital so they had to convert a rest-house situated in the Mussulman cemetery into one, a place which, as the old Wykehamist says with grim humour, was "very handy, for the cases usually die in under five days." Eventually he got an English surgeon to help him who had a rather bad time for the first few weeks, for he was imbued with modern ideas as to stethoscopes and thermometers which naturally appalled the intensely conservative Oriental mind. However, this wore off and when the epidemic was over he was *fêted* by the very people who had previously looted his house and this, too, after having been smitten by the plague himself. The old Wykehamist was obviously endued with the dogged British pluck which a public school education affords a man. "I dug up lots of bodies when concealed plague was suspected. Sometimes a body would be left unclaimed in a house and I had to shoulder it and bring it out myself. One day I built a very fine funeral pyre myself and roasted a gentleman. ....." Winchester may well be proud of her son: and the editor of *The Wykehamist* is to be congratulated upon his magazine for it is certainly superior to the usual run of school journals.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received: *Evesham Journal, Rugby Advertiser, Leicester Post, Wilts County Mirror, Hampshire Advertiser, Batley News, Dewsbury Reporter, Lowestoft Standard, Kenilworth Advertiser, Times of India, Pioneer Mail, Scotsman, Citizen, Weston Mercury, Keene's Bath Journal, Leeds Mercury, Builder, Liverpool Daily Post, Cheltenham Free Press, Newcastle Leader, Architect, Bury Guardian, Brecon County Times, Bristol Mercury, Essex Telegraph, Walsall Observer, Yorkshire Post, Local Government Chronicle, Derby Times, Todmorden News, Pullen's Kent Argus, Eastern Morning News, Orsett Observer, Wigan Examiner, Kentish Gazette, South Wales Guardian, Lynn News, Guernsey Star, Hemel Hempstead Gazette, Midland Counties Express, Retford Times, Birmingham Post, Kidderminster Sun, Brighton Gazette, Sanitary Record, Meath Herald, City Press, Shipley Times, Reading Mercury, Hertfordshire Mercury, Australian Medical Gazette, Local Government Journal, Portadown News, Southampton Observer, Alfreton and Belper Journal, Surrey Advertiser, Surrey Comet, Lloyd's Weekly Newspaper, Devon County Standard, &c., &c.*

SURGERY, DENTISTRY, BIOLOGY, AND ALLIED SCIENCES.

"A highly valuable piece of work."—THE LANCET.
". . . Such a classic work."—BRITISH MEDICAL JOURNAL.
"An epoch-making work of reference."—MEDICAL PRESS.
"The author has fulfilled his supremely difficult task admirably, and has evidently spared no pains to present and to explain every technicality."—THE TIMES.

With 84 Illustrations, royal 8vo, price 25s.

Kaposi's Skin Diseases.

Authorised Translation from the latest German Edition of Professor KAPOSI, of Vienna University.

"Now the standard authority on skin diseases."—THE LANCET.
"A serious, conscientious work upon which student and practitioner can alike rely."—NEW YORK MEDICAL RECORD.
"The work of a writer who occupies the foremost rank among European Dermatologists."—MEDICAL PRESS.
"The standard book of reference."—MEDICO CHIRURGICAL JOURNAL.

Just out, Fifth Edition, with 547 Coloured Illustrations, 31s. 6d. net.

The Throat and Nose
AND THEIR DISEASES.

By LENNOX BROWNE, F.R.C.S.E.,
Senior Surgeon to the Central London Throat, Nose, and Ear Hospital.

"The best and most practical treatise on diseases of the throat in any language."—BRITISH MEDICAL JOURNAL.
"The most striking feature in this work—apart from the individuality of the author—is the excellence of the illustrations."—DUBLIN JOUR. OF MED. SCIENCE.

Now ready, price 10s. 6d.

Murrell's Pharmacology and
THERAPEUTICS.

A Manual Specially Designed for the Examinations.

By WM. MURRELL, M.D., F.R.C.P.Lond., Physician to Westminster Hospital.

"The author's genial style confers a glamour even on the dry details of pharmacology."—MEDICAL PRESS AND CIRCULAR.
"This manual will become a favourite with students."—EDINBURGH MEDICAL JOURNAL.

Ninth Edition. Revised, enlarged, and brought up to date.

Naphey's Modern Therapeutics.

dited by Drs. ALLEN SMITH and AUBREY DAVIS.
Two Vols., bound half morocco.

Applied Bacteriology:

A MANUAL FOR STUDENTS AND PRACTITIONERS.

Containing the latest Methods of Research and their application.

By T. H. PEARMAIN and C. G. MOOR, M.A.Cantab., F.C.S., F.I.C. With 81 Illustrations in Colours.

"The authors have selected and arranged their material with judgment, and have succeeded in presenting it in a scientific spirit."—BRITISH MEDICAL JOURNAL.
"The fact that this very practical manual supplied a definite want in scientific literature is amply proved by the early call for a second edition."—THE MEDICAL PRESS.

Just out. Second Edition, 486 pp., with Illustrations, price 12s. 6d. net.

Diseases of the Stomach.

A TEXT-BOOK.

By MAX EINHORN, M.D.,
Professor in Clinical Surgery in the New York Post-Graduate School.

"The book is one that should be in the hands of all practitioners of medicine who wish to know how stomach diseases are now diagnosed and treated."—BRITISH MEDICAL JOURNAL.
"A thorough survey of the whole subject."—THE LANCET.

Third Edition. Just out, with Coloured Plates, price 15s. net.

Manual of Physiology.

By Professor G. NEIL STEWART, M.A. Cantab., M.D., D.Sc., formerly Director of the Museums, Cambridge University, and Examiner in Physiology, Aberdeen University; now Professor of Physiology in the Western University, United States.

"It is one of the very best English text-books at the command of the student."—THE LANCET.
"We do not know of one that comes up to the ideal text-book as does Professor Stewart's volume."—BRITISH MEDICAL JOURNAL.

London: BAILLIÈRE, TINDALL, & COX, 20 and 21, King William Street, Strand.

Just published, THIRTEENTH Edition, thoroughly revised, 8vo, 16s.

A HANDBOOK OF THERAPEUTICS. By Sydney Ringer, M.D.,

F.R.S, Holme Professor of Clinical Medicine in University College; Physician to University College Hospital; and HARRINGTON SAINSBURY, M.D., F.R.C.P., Physician to the Royal Free Hospital, and the City of London Hospital for Diseases of the Chest, Victoria Park.

"Of Dr. Ringer's well-known 'Handbook of Therapeutics' we can only speak generally in terms of praise. The first edition was not published until 1869, but we have no hesitation in saying that it has practically revolutionised the science of which it treats. ..... Ringer's Therapeutics will always be popular, both with practitioners and senior students."—THE LANCET.

FOURTH Edition, with Illustrations, 8vo, 10s. 6d.

On Deafness, Giddiness, and Noises in the HEAD.

By EDWARD WOAKES, M.D. Lond., Senior Aural Surgeon, London Hospital; Lecturer on Diseases of the Ear, London Hospital Medical College; assisted by CLAUDE WOAKES, M.R.C.S., L.R.C.P., Assistant Surgeon to the London Throat Hospital.

SEVENTH Edition, crown 8vo, 4s. 6d.

Gout and its Relations to Diseases of the LIVER and KIDNEYS.

By ROBSON ROOSE, M.D., F.R.C.P.Ed.

"It is one of the clearest and most complete reviews, in a small space, of existing knowledge with regard to this disease which we remember to have read, and it may be strongly recommended to the study of the young practitioner."—BRITISH MEDICAL JOURNAL.

Cloth, 310 pp., 32mo, 2s. 6d. net. (post-free, 2s. 8d.)

A Pocket Medical Dictionary, giving the

Pronunciation and Definition of about 12,000 of the Principal Words Used in Medicine and the Collateral Sciences. By GEORGE M. GOULD, A.M., M.D., Author of "The Student's Medical Dictionary," &c.

"A very reliable and complete work."—MEDICAL PRESS.
"It is both full, useful, and complete."—MEDICAL TIMES.

With Illustrations, small 8vo, 5s. 6d.

A Guide to the Examination of the Nose;

with REMARKS on the DIAGNOSIS of DISEASES of the NASAL CAVITIES. By H. CRESSWELL BABER, M.B.Lond., Surgeon to the Brighton and Sussex Throat and Ear Dispensary.

GEORGE'S PATENT CALORIGEN,

For WARMING & VENTILATING. GAS CALORIGEN, £3 3s. Height, 28 in.; Diameter, 14 in.

The PATENT SLOW COMBUSTION CALORIGEN. Price £6 6s. Will burn Anthracite Coal or Coke for twelve hours without attention. No escape of fumes when feeding.

Manufacturers: J. F. FARWIG & CO., CALORIGEN WORKS, 4, Upper Thames-st., E.C. (opposite "The Times" Office).

The Stoves introduce a strong current of warmed (not burnt) fresh air, and are recommended by the Medical Profession.

"5, Gledhow-gardens, South Kensington, Dec. 9th, 1886.

"After more than ten years' experience of the Patent Calorigen in my own house and in those of a great number of my patients I think it due to you to express, unsolicited, the opinion that it is one of the most valuable heating apparatus ever introduced. For night use in the sick room I know nothing to compare with it. In all cases of chronic asthma and bronchitis I regard it as a therapeutic agent of the first importance. Provided with a Calorigen, the patient can breathe fresh summer air day and night without leaving his room. I have never yet written a certificate for publication, but you are at liberty to make any use you like of this expression of opinion.

INSTRA WARMERS.

PATENTED THROUGHOUT THE WORLD. PRIZE MEDALS AT EXHIBITIONS (BRITISH AND FOREIGN).

A SEASONABLE PRESENT, COMBINING UTILITY WITH ORNAMENT.

The small Pocket "INSTRA," weight 3½ oz., is invaluable as a Preventative against Chills, the extra warmth enabling a person to go about ordinary avocations when suffering from cold without after ill-effect. Used by Travellers, Sportsmen, persons driving, &c., and wherever changes of temperature are encountered. Larger sizes for Footwarmers and other purposes are supplied.

Surgeon-General Sir W. MACKINNON, K.C.B. (late Director of the Army Medical Department) writes:—

"I went out one cold day without a great-coat, carrying the 'Instra' in a side pocket, and it kept me warm and comfortable. I then came in and sat in a cold room without a fire, still having the 'Instra' in my pocket, which kept me quite warm. If we had had such a thing in the Crimea during our first winter, what a blessing it would have been for our troops! ..... I shall recommend it to my friends."

Rev. G. E. M. EVANS writes:—

"Penryn, Cornwall, April 8th, 1897.

"I am very pleased with the 'Instra.' I have been caught in the rain on my bicycle two or three times, and by carrying the 'Instra in my pocket have felt no chill and caught no cold."

Miss GRACE METCALFE-WHITE writes:—

"3, Antrim Mansions, Haverstock-hill, N.W., 4th Feby., 1898.

"I found the 'Instra' invaluable in travelling, in hotels, in freless rooms, and even in ordinary daily walks and shopping. Fastened in the muff, it kept me in a warm glow all the time."

JAMES J. HICKS,

FOR SCIENTIFIC INSTRUMENTS.

INSTRUMENT MAKER to the WAR OFFICE, ADMIRALTY, INDIA OFFICE, &c., &c., &c.

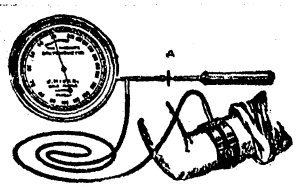

FIG. 1.

THE NEW PATENT SPHYGMOMETER,

by Drs. HILL and BARNARD, is of special construction and a simple and accurate arterial pressure gauge. It is marvellously sensitive, and consists of a metal tambour the expansion of which is exhibited in a highly magnified form by means of an index or pointer which travels round a dial. The dial is graduated in millimetres of mercury. The armlet, pump, and pressure gauge fit conveniently into a leather case when not in use. By means of this instrument the arterial pressure can be taken in man as rapidly, simply, and accurately as the temperature can be taken with the clinical thermometer.

Price of Sphygmometer, £5.
Spare Bag and Tube, 5s

Descriptive Pamphlet of Sphygmometer, with hundreds of experiments by various doctors, now ready, sent *free* on application.

ONE SHAKE WILL SET IT!

FIG. 3.

HICKS'S PATENT "FACILIS" CLINICAL THERMOMETER

Is the best Thermometer of the day and the *original* of its kind for simplicity and ease in working. It requires ONLY ONE SWING TO SET THE INDEX after use. Amongst many so-called improvements recently offered to the public this Thermometer is the only one that is any good and that will not speedily get out of order. This Thermometer is simply *perfect* in its action, has a nice *open* scale, giving wide divisions which are very easy to read, and is made either with or without the magnifying tube. Every one of them is *guaranteed accurate to one-tenth part of a degree*, is made of specially seasoned glass, and with care should last a lifetime. The success that has attended its introduction has been altogether unprecedented, the demand far exceeding the supply. All that infinite knowledge of the subject can suggest and the highest skill in manipulation can effect have been employed on this Thermometer to make it the *very best*, and its popularity will be as *permanent* as it is great.

TO BE OBTAINED OF ALL CHEMISTS AND STORES, SURGICAL & OPTICAL INSTRUMENT HOUSES, &c., &c.

8, 9, & 10, HATTON GARDEN, LONDON, E.C.

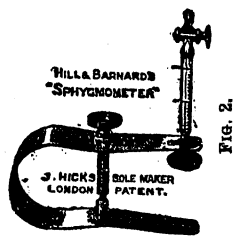

FIG. 2.

This Instrument has been devised by Drs. HILL and BARNARD for use on the wrist. It retains all the valuable points of Fig. 1, but is made in a more portable form for convenience, so that it can be carried in the pocket with ease. The instrument is used in a vertical position on the wrist, the rubber bag being pressed upon the radial artery until the maximal pulsation is obtained. It is exceedingly simple to use, marvellously sensitive, and as accurate and reliable as a clinical thermometer.

Price of Sphygmograph only, in neat morocco case, 30s.
Clamp for Wrist, extra, 6s. 6d.

Both Fig. 1 and Fig. 2 have met already with much success and been adopted by a large number of the Medical Profession.

Descriptive Price List *free*.

THE INVENTION OF THE AGE.

"Sparklets"

(SMALL STEEL RECEIVERS CONTAINING THE PUREST COMPRESSED CARBONIC ACID GAS).

FOR THE INSTANTANEOUS AERATION OF ALL LIQUIDS,

WATER, MILK, BARLEY WATER, LIGHT WINES, &c., &c.

One "Sparklet," when used with Special Bottle supplied for the purpose, will at once strongly aerate water more than the liquid contained in a large-sized Soda Water Bottle. (Two of the Special Bottles equal to three full-size Sodas.)

INVALID DRINKS CAN NOW BE DIRECTLY AERATED (NO DILUTION) AS REQUIRED, MAKING THEM MUCH MORE REFRESHING AND EASIER OF DIGESTION.

Tuberculosis.—Milk which has been boiled can be directly aerated (no dilution).

Purity of liquid controlled by the operator.

Water, which has been boiled or distilled, can now be made with "Sparklets" as refreshing and palatable as the finest spring water.

Members of the Medical Profession will at once recognise the great value of this invention.

Having once purchased the Special Bottle costing 4s 6d., all that is afterwards necessary is supplies of "Sparklets" costing 1s. per box of one dozen.

☞ **A Sample Bottle, with two boxes of "Sparklets" will be sent carriage paid to any Member of the Medical Profession at half price (viz., 3s. 3d.), provided the application is received by the Patentees on or before the 14th January, 1899.**

52 Highest Awards over all Competitors throughout the World.

SEABURY & JOHNSON,

ORIGINAL MANUFACTURERS OF

Pharmacopœial and Surgical Plasters

IN RUBBER COMBINATION,

ANTISEPTIC DRESSINGS & ABSORBENTS, &c.

THROUGHOUT THE WORLD

SEABURY'S BELLADONNA PLASTERS

ARE PROVEN OF FULL AND DEFINITE ALKALOIDAL STRENGTH,

therefore of full therapeutic power. The analytical laboratories prove their absolute reliability and uniformity—they prove the contrary of others. Thus we justify our claims that **SEABURY'S** are "**THE BEST**," and, as we stand ever ready to substantiate them, we doubt not that the profession and trade will value them accordingly.

"The Best" is none too good in medicine and food, and the conscientious pharmacist cannot afford to hazard his reputation by buying articles the very price of which, as compared with those of established reputation, is sufficient evidence of inferiority. If, however, the difference in price leaves any doubt in the mind of the pharmacist or physician as to the difference in quality, let him make the most critical and exacting tests, and be convinced.

Report of THE LANCET, December 3rd, 1898:—

"Seabury & Johnson's Belladonna Plasters are not only satisfactory on account of the excellence of the rubber basis, but—of more importance still—are standardised in regard to the constituents of Belladonna, the yield of alkaloids on analysis being just slightly over half per cent. in accordance with pharmaceutical requirements. These Plasters may therefore be relied upon."

SEABURY & JOHNSON,

HAVE FOR YEARS MAINTAINED '5 PER CENT. OF BELLADONNA ALKALOIDS AS THE MINIMUM STANDARD STRENGTH FOR THEIR BELLADONNA PLASTERS.

It has become common for Plasters to be offered to the trade labelled "Belladonna Plasters" which contain scarcely any of the alkaloid, and in many cases *absolutely none,*

When ordering, specify "SEABURY'S," and, in addition to this precaution, refuse to take any other make.

SOLE DEPÔT FOR GREAT BRITAIN AND COLONIES—

FASSETT & JOHNSON, 31 & 32, Snow Hill, LONDON, E.C.

Antikamnia

OPPOSED TO PAIN

(Cn H2n-6)

A succedaneum for morphia.

Does not depress the heart.

Indications:

"in the treatment of melancholia with vaso-motor disturbances, anæmic headaches, emotional distress, and active delusions of apprehension and distrust.

"In neurasthenia, in mild hysteroid affections, and in the various neuralgias, particularly ovarian, in the nervous tremor so often seen in confirmed drunkards, it is of peculiar service.

"In angina pectoris this drug has a beneficial action it relieves the pain and distress in many cases, even when amyl nitrite and nitro-glycerine have failed entirely. In pseudo-angina, frequently observed in hysterical women, its action is all that can be desired.

"In delirium tremens, it relieves when there is great restlessness with insomnia, as well as general lowering of the nervous power."

Average Dose:

of Antikamnia is two tablets, five grains each, and more prompt results will be secured by crushing the tablets before swallowing. Tablets should never be swallowed whole.

Marketed:

in powder and tablets (5 gr. & 3 gr.) in 1 oz. original packages only. Professional prices and for dispensing purposes: 3/9, post free 3/10. ANTIKAMNIA CHEM. Co. (St. Louis). British Depôt: 46, Holborn Viaduct, E.C.

Skeleton Calendars:

a few still in hand (1898) will be sent to first applicants.

THE LANCET

On ANTIKAMNIA.

"Antikamnia is well spoken of as an analgesic and antipyretic in the treatment of neuralgia, rheumatism, &c. As may be imagined, it is one more addition to the already long list of coal-tar derivatives of the benzene series, into which, however, certain amine groups have been introduced. It is a white powder of a bitter taste and alkaline reaction. It is not disagreeable to take, and may be had either in powder or tablet form, the latter being made in 5-grain size. It is described as not a preventive of, but rather as affording relief to existent, pain. By the presence in it of the amine group it appears to exert a stimulating rather than a depressing action on the nerve centres and the system generally. If this be so, it possesses advantages over other crystalline coal-tar products."

DUNCAN'S CHLOROFORM.

ALTERATION OF LABEL.

Below we append facsimiles of the labels now in use.

CHLOROFORM DUNCAN'S PURE S.G. 1·490. PREPARED ENTIRELY FROM BRITISH ETHYLIC ALCOHOL BY DUNCAN, FLOCKHART & CO., EDINBURGH & LONDON.	*NOTE.*—This, which is prepared entirely from British Ethylic Alcohol, is the only CHLOROFORM which we supply as *Duncan's Pure*, S.G. 1490. To be kept Cool, and not exposed to a Strong Light. POISON.	THIS LABEL IS PRINTED IN BLACK INK.
CHLOROFORM DUNCAN'S METHYLATED S.G. 1·490. PREPARED ENTIRELY FROM METHYLATED SPIRIT BY DUNCAN, FLOCKHART & CO., EDINBURGH & LONDON.	*NOTE.*—This CHLOROFORM answers the tests of the British Pharmacopœia, but it must *not be confounded with* "DUNCAN'S PURE," which is prepared entirely from Ethylic Alcohol. To be kept Cool, and not exposed to a Strong Light. POISON.	THIS LABEL IS PRINTED IN BLACK INK ON ORANGE PAPER.

DUNCAN, FLOCKHART, & CO.,

That Medical Man is yet to be found who after investigation and trial fails to fully endorse the claims made for

FELS'S GERMICIDE SOAP.

Nearly three thousand letters of approval have been received from the Medical Profession of Great Britain, showing that in Obstetrics, most forms of Skin Diseases, in Dental Practice, as a Germicide, as a Deodorant, and in numerous other uses, including the Toilet,

FELS'S GERMICIDE SOAP

stands alone.

It contains **HYDRARG. BICHLORID., SAL. ALEMBROTH, B. NAPHTHOL, and EUCALYPTOL.**

Every Physician who tests it believes in it.

Every modern Chemist stocks it and sells it at protected prices.

All Wholesale Houses supply it.

1/- per CAKE; 8/4 per Dozen.

CHINOSOL

ANTISEPTIC DISINFECTANT DEODORANT.

NON-POISONOUS. NON-CORROSIVE. NON-VOLATILE. READILY SOLUBLE. VERY PORTABLE. ECONOMICAL.

A large circle of the **Medical and Surgical Profession** have now finally adopted the use of **CHINOSOL** in preference to Corrosive Sublimate and Carbolic Acid. **CHINOSOL** is supplied to the **Metropolitan and Counties Asylum Boards, Infirmaries, Hospitals, Schools,** &c., for **Inodorous Disinfection** and General **Sanitation.** The **non-poisonous** and **non-corrosive** character, the important **germicidal** and **deodorising** power and the **great portability** of **CHINOSOL** are no doubt some of the points which gain for it a daily increasing number of patrons.

NOTICE.—Each Package of CHINOSOL Preparations bears full instructions, and where these have been removed, a fresh copy will be sent on application.

TANNALBIN

(KNOLL.)

This non-toxic **INTESTINAL ASTRINGENT** and **ANTI-DIARRHŒAL** occurs in the form of a light-brown powder, which is insoluble in the gastric juice and only slowly soluble in intestinal fluids; it causes no disturbance in the stomach, no nausea, no anorexia; it is tasteless, odourless, and is readily taken by adults and children. Dr. von ENGEL, Brunn, and Prof. Dr. VIERORDT, University Clinic, Heidelberg, and many other observers recommend **TANNALBIN in all cases of Sub-acute and Chronic Enteritis, whether of Children or Adults, as it unquestionably deserves the first place among astringent medicines.** See pamphlet just published: *Hints on the Use of Tannalbin* (1) in Acute, Subacute, and Chronic Enteritis, Dysentery; (2) in Diarrhœa of Phthisical Patients; (3) in Diarrhœa of Infants and Children; and (4) its Preventive use in conjunction with other remedies. Tannalbin is supplied in powder and 5-grain tablets, the latter is most convenient for prescribing.

PAPAÏN-FINKLER.

This ideal purely vegetable digestive ferment is largely used in the curative treatment of **Gastric Ulcer** (THE LANCET, Feb. 9th, 1895, p. 333), and as an aid to the nutrition of patients suffering from **Phthisis,** its value cannot be overrated (see THE LANCET, April 27th, 1895, page 1050). The solvent action of Papaïn on albuminous bodies is also turned to account in Diphtheria. Under the application of a 5 per cent. aqueous mixture the false membranes promptly disappear, leaving the mucous membrane accessible to the action of suitable antiseptics. The importance of this effectual local treatment is in no wise diminished by the constitutional effects of the Antitoxin treatment. Papaïn is further indicated in all forms of dyspepsia, its action being fully maintained in acid, alkaline, and neutral medium, exhibiting at the same time a tonic and antiseptic effect.

COLCHI-SAL.

(Colchicine (Methyl) Salicylate).

FOR SUBACUTE, CHRONIC, & ARTICULAR PERICARDITIS, PLEURISY, LUMBAGO,

BETUL-OL.

(Lin. Methyl Salicyl. Comp.).

RHEUMATISM, RHEUMATOID ARTHRITIS, SCIATICA, GOUT, & ALLIED AFFECTIONS.

COLCHI-SAL CAPSULES.—The difficulty of administering this compound as a remedy in Gouty and Rheumatic Affections has been overcome by dispensing the same in small, accurately dosed capsules. Each capsule contains $\frac{1}{200}$ grain chemically pure **Colchicine** dissolved in 3 grains of Natural Methyl Salicylate from Betula Lenta, equivalent to 5 grains Salicylate of Soda.

BETUL-OL.—An Anodyne Compound Liniment of Methyl Salicylate, specially prepared in such a way that it is absorbed almost as soon as applied to the skin. To supplement the action of Colchi-Sal and to replace Salicylate of Soda, when this salt is not tolerated internally. Colchi-Sal Capsules and Betul-Ol are dispensed only on prescription.

Above Preparations are Sold by all Wholesale and Retail Chemists; where not promptly obtainable please apply direct to

THE ORIGINAL
Petroleum Emulsion.

Introduced to the Medical Profession of Gt. Britain in 1892.

CAUTION.

The success of **ANGIER'S PETROLEUM EMULSION** has, as is usual in such cases, led to widespread imitation and substitution, and it is therefore necessary to offer a few words of caution.

Medicinal petroleum preparations are our speciality, and Angier's Emulsion is but one of a number of such preparations manufactured by our house at Boston, U.S.A. We purify our own oil by a special process of our own, and know that we have a product not obtainable by manufacturing chemists generally. The numerous imitations now offered for sale are probably made with some one of the ordinary petroleum oils of commerce, which were never intended by the refiners for internal administration, and which in our opinion are wholly unfit for such a purpose. In fact, owing to imperfect methods of treatment, or to the presence of impurities, their use in some cases might even prove harmful. We therefore strongly urge medical men when prescribing to specify **ANGIER'S** Emulsion, for otherwise some imitation made with ordinary petroleum might be substituted, and disappointment be the result.

PEPSENCIA.

PEPSENCIA is an ever-ready digestive fluid, containing all the soluble constituents of the gastric juice, preserved in an agreeable aromatic menstruum. It represents both the peptic and milk curdling ferments obtained directly from the fresh peptic glands.

PEPSENCIA is acceptable to the most delicate and fastidious patient, while it excels all other allied preparations in activity and utility.

One teaspoonful before or after a meal will be found of service in all cases where pepsin is indicated.

Supplied to the Medical Profession in 4 oz. and 8 oz. bottles, at 1s. 9d. and 3s. each.

* * * * * * * * * * * *

Peptogenic Milk Powder.

Cows' milk prepared with PEPTOGENIC MILK POWDER becomes remarkably like mothers' milk in all particulars: in physical properties, in colour and taste, and in the percentage of nutritive constituents: in its digestibility, its behaviour with acid, with rennet, and in the infant's stomach.

Milk prepared with the PEPTOGENIC POWDER has simply the normal digestibility of mothers' milk: is not too easily or unnaturally digestible, and contains no aid to digestion. It affords a complete substitute for mothers' milk during the entire nursing period.

Supplied to the Medical Profession in two sizes, at 1s. 9d. and 3s. 4d. each.

Specimens and Literature will be forwarded on request.

Originated and Manufactured by

FAIRCHILD BROS. & FOSTER,

NEW YORK.

SOMATOSE

is an Albumose Food product. It is prepared from meat, and contains the albuminous elements of the latter in an easily soluble form. The salts present in SOMATOSE correspond to the nutritive salts of fresh meat, among which occur Phosphate of Potassium, so important in the formation of muscular and cellular tissue.

SOMATOSE is a Tasteless, Odourless Powder,—is easily tolerated, even by the most delicate stomachs. It is invaluable in Wasting Diseases, and is especially indicated in Children of Backward Development.

SOMATOSE is well borne when no other aliment can be administered. It is also of the greatest service in cases requiring rectal alimentation.

SOMATOSE has been found to act as a most efficient Galactogogue. Remarkably successful results attending its use when administered to nursing women whose milk secretion is deficient or scanty.

SOMATOSE is indicated in all conditions where an invigorating and easily absorbed food is required. With the aid of SOMATOSE it is possible to tide the patient over critical periods, since it is capable of acting for a long time as a complete substitute for other nitrogenous foods.

ADULT DOSE: One teaspoonful three times a day, in milk, soup, coffee, cocoa, &c.

The following is the Analysis of SOMATOSE as obtained by Goldman:—

Water	9·20
Total Nitrogen	12·84
Albumoses	77·85
Peptone	2·20
Ash	6·78

IRON-SOMATOSE

(Ferro-Somatose).—An excellent tonic, containing the albuminous substances of the meat (albumoses) organically combined with Iron in the proportion of 2 per cent. of the latter. Under the use of Iron-Somatose the weight of the body is increased and the amount of hæmoglobin is augmented. Iron-Somatose combines in a most suitable way the well-known and appreciated properties of Somatose with a good Iron preparation.

SPECIAL INDICATIONS: Chlorosis and Anæmia. DAILY DOSE: 75 to 150 grains.

MILK-SOMATOSE

(Lacto-Somatose).—A strength-giving food containing the albuminous matter (albumoses) of the Milk, with 5 per cent. of Tannic Acid in firm organic combination. The chief indications of Milk-Somatose are the various chronic maladies of the digestive organs, and especially those disturbances of digestion which, as in Enteroptosis and Anæmia, can be referred to the atonic condition of the muscular organs of the stomach. Milk-Somatose is a good flesh-forming preparation, without irritation, and slightly astringent with patients of weak or diseased digestive organs. In the case of Typhus maladies it is of great value.

BAYER'S
PHARMACEUTICAL SPECIALITIES

TRIONAL. (*Diethylsulfonmethylethylmethan*).—A most reliable and quickly acting hypnotic of the Sulfonal group. In simple insomnia Trional will produce sleep with absolute certainty in from fifteen to thirty minutes. Has no influence on the heart, respiration, or temperature. DOSE: From 15 to 30 grains, followed by a hot drink. Oxycarbonated Trional Water, manufactured by Messrs. Cooper & Co., 80, Gloucester-road, S.W., is recommended as a good and agreeable method of administration. In this form a smaller dose suffices.

TANNIGEN. (*Triacetyl of Tannin*).—A most valuable remedy in cases of Acute and Chronic Diarrhœa, and invaluable for the Summer Diarrhœa of Children. Tasteless and Odourless. Passes through the stomach entirely unchanged, decomposition only occurring in the intestines. DOSE FOR CHILDREN: 2 to 5 grains. DOSE FOR ADULTS: 8 grains every three hours.

TANNOPINE. (*Hexamethylene-tetramine Tannin*).—A New Intestinal Astringent. Has an excellent effect, without secondary phenomena, in all the various kinds of Enteritis. Has given especially good results in cases of Tuberculous Inflammation of the Bowels, in cases of Non-Tuberculous, Subacute and Chronic Intestinal Inflammation, and also in cases of Typhoid. DOSE FOR CHILDREN: 3 to 10 grains. DOSE FOR ADULTS: 16 grains, two to four times daily.

SALOPHEN. (*Acetyl-para-amydosalol*).—The best substitute for Salicylate of Sodium, as it acts quite as promptly, but without any of the unpleasant after-effects of the latter. Its special indication is Acute Articular Rheumatism. It is invaluable for Influenza, Migraine, &c. DOSE: 16 to 24 grains three or four times a day.

LYCETOL. (*Tartrate of Di-Methyl-Piperazine*).—Combines the Uric Acid solvent properties of Piperazine, with the diuretic properties of Tartaric Acid. Invaluable in all cases of Uric Acid Diathesis. DOSE: 16 to 32 grains daily. Best administered in the form of Effervescing Lycetol, Messrs. A. Bishop & Sons. Ltd., Spelman-street, E.; or Oxycarbonated Lycetol Water, Messrs. Cooper & Co., 80, Gloucester-road, S.W.

IODOTHYRINE. The active principle of the Thyroid Gland. A stable product containing a definite amount of the Iodine compound which forms the active principle of the Gland. Iodothyrine acts more quickly than either the fresh or dried gland substance. It is a preparation of perfectly definite composition, stable and permanent. ADULT DOSE: 5 grains two to eight times a day. Prepared also in Tablet form.

CREOSOTAL. (*Creosotum Carbonas puriss.*).—A mixture of the phenol carbonates of creosote. Most valuable in Tuberculosis of the lungs. DOSE: ½ to 5 drachms per day in wine, brandy, or cod-liver oil.

DUOTAL. (*Guaiacolum Carbonas puriss.*).—Great success in cases of Pulmonary Phthisis. DOSE: 8 to 96 grains per day.

HEROIN. (*Ester of Morphine.*)—An excellent Substitute for Morphine. Most satisfactory results in cases of Bronchitis, Pharyngitis, Laryngitis, Catarrh of the Lungs in Phthisical persons, and in Asthma Bronchiale. DOSE: 0 005 gramme, from 3 to 4 times daily. In the latter two cases the dose may be increased to 0.01 gramme.

EUROPHEN. (*Isobutylorthocresoliodide.*)—A perfect substitute for Iodoform. Odourless and non-toxic. Five times lighter than Iodoform. Non-irritating and does not produce a rash. Adheres closely to mucous surfaces. Specially indicated in Syphilitic Diseases, Gynæcology, Burns and Bedsores, Eye, Ear, Throat, and Nose Affections, &c., &c.

ARISTOL. An Iodine Derivative containing 48% of Iodine. Is an ideal Cicatrisant, forming an absolutely unirritating covering over the surfaces on which it is placed, under which the processes of granulation and cicatrization proceed with extraordinary rapidity. It is a convenient, Non-Irritating and Effective Antiseptic Dressing in General Surgery, Dentistry, Gynæcology, Diseases of the Eye, Ear, and Nose. In the treatment of Burns, Aristol has proved to be of the greatest value, its antiseptic and healing properties being specially marked.

PROTARGOL. A new proteid compound of silver for the treatment of Gonorrhœa, containing 8% of silver, easily soluble in warm or cold water. Has a better penetrating effect on the tissues than any other known silver preparation. Non-irritating. Usual strength of injection, ¼ to 2%. An excellent antiseptic in the treatment of Wounds. Of the greatest possible service in Ocular Therapeutics. Protargol is manufactured in Bougie form by Messrs. Sumner & Co. of Liverpool, and Mr. R. Manson, 75, Fortess-road, Kentish-town, N.W., from whom samples may be had.

PHENACETINE-BAYER, SULFONAL-BAYER, PIPERAZINE-BAYER, SALOL-BAYER, SOMATOSE, IRON SOMATOSE, MILK SOMATOSE, ANALGEN, LOSOPHAN, TETRONAL, &c.

Samples and Literature can be had on application to the Wholesale Depôt for all Bayer's Drug Specialities:—

HIGH-CLASS PHARMACY.

SAVARESSE'S CAPSULES.

NOT MADE OF GELATINE.

Being made of MEMBRANE, they are free from the objections to all Gelatine Capsules.

SANDAL WOOD OIL, 4/6.

COPAIBA, 2/6.

SAVARESSE'S Capsules of ORGANIC MEMBRANE do not dissolve in the stomach (avoiding nausea and irritation), but generally in the intestines.

The late Mr. W. ACTON, F.R.C.S. (p. 96, "Urinary Diseases"), recommended them.

SAVAR'S Cubeb Cigarettes.

For Asthma, Chronic Cough, Influenza, and Hay Fever, Cubebs smoked so far as to get the effect of the resins down the throat are always worth a trial. 1/- and 2/6 boxes.

MONTSERRAT LIME-FRUIT JUICE

True Lime Fruit Juice is a very useful acid drink, when diluted. The best is from the Consignee's Estate in Montserrat, W.I., of which over 100,000 gallons annually come over to the Sole Consignees. It is pure, reliable, pleasant, and a genuine anti-scorbutic. Imperial Pints and Quarts.

PRESCRIBE CASCARA-HAWLEY FOR CONSTIPATION.

A reliable Laxative is often wanted (especially for Ladies and Children). Nothing can be better than the B.P. Fl. Extract of Cascara Sagrada, rendered tasteless by an envelope of gelatine, equal to ½ drachm of fl. extract. In Pregnancy and Habitual Constipation invaluable. 1/1½ and 4/6 boxes.

SAVAR'S COCA WINE

WHAT COCA WINE SHALL WE ORDER?

SAVAR'S, brought out in 1875, is standardised to contain ½ grain pure Cocaine in each fl. oz., and 2 fl. drachms is a dose. Many Coca Wines *cannot* be sold by chemists without a wine licence, because so weak in Cocaine—SAVAR'S *can*. Physicians know exactly what they are doing in ordering this stimulating tonic.

Bottles 4/- and 7/-.

EVANS' FLUID EXTRACTS.

The Perfection of Pharmacy. Made with special menstrua, they represent weight for weight of the crude drug, of which they contain the *whole* of the medicinal properties. Always reliable; keep well. Tinctures and infusions can be immediately prepared from them, one minim representing one grain of the drug. Full List, with Doses, &c., on application.

Lescher's Recent Materia Medica, 4th Edition, 500 Drugs, with Doses, Formulæ, &c., 2/6.

The "Allenburys" TRADE MARK. A.D. 1715.

Throat Pastilles.

SOFT. DEMULCENT. PALATABLE.

THESE PASTILLES have now for many years been employed by the Faculty in the relief of Throat Affections. Their form enables them to be more easily sucked than the ordinary hard lozenge; while the Pâte de Jujube from which they are manufactured is particularly palatable, soluble, and demulcent in its action.

Owing to the accumulated prescriptions and suggestions of Physicians and Specialists on the throat, ALLEN & HANBURYS are enabled to manufacture upwards of fifty varieties to meet various morbid conditions. Each variety has a specified number in the List, where the prescriptions are quoted in full. The following are examples of the Pastilles in very general use.

In prescribing it is only necessary to add the letters A. & H., these being registered as a Trade Mark; thus—Tannin Pastilles A. & H.

No. 9. Menthol, Cocaine, and Red Gum. *Menthol et Cocainæ, aa. gr. 1/10; Gummi Rubri, gr. ii.*
Antiseptic, Sedative, and Astringent.

" 11. Chlorate of Potash. *1 grain in each.*
Better than the B.P. form.

" 27. Compound Eucalyptus.
(Red Gum, Chlorate of Potash, and Cubebs). A valuable astringent.

" 29. Compound Rhatany and Cocaine. *Ext. of Rhatany grain 2, Cocaine Hydrochlor. grain 1/10th.*
A very efficacious astringent and anodyne.

" 38. Cocaine, Chlorate of Potash, and Borax.
Especially useful for the tickling of a slightly relaxed throat.

" 44. Menthol and Cocaine. *1/10th of a grain of each in a Pastille.*
The antiseptic and stimulating action of the Menthol, combined with an effective Anodyne.

" 45. Menthol & Rhatany. *1/10 of a grain of Menthol in a Pastille.*
Stimulating, antiseptic, and mildly astringent.

" 46. Tannin, Cayenne, and Black Currant.
Is far more palatable and efficacious than the ordinary lozenge.

MANUFACTURED BY

Allen & Hanburys Ltd., Plough Court, Lombard Street, London.

"A distinct advance on Easton's Syrup."—*The Lancet.*

Bynin Amara.

TRADE MARK.

This preparation is a greatly improved modification of the well-known Easton's Syrup, in which the Phosphates of Iron, Quinine, and Strychnine are united with **BYNIN (Liquid Malt)**, affording at one and the same time a specific digestive, restorative, and anti-febrile tonic. The nervous system is restored in tone, the enfeebled blood corpuscles are strengthened, and the digestive apparatus is helped and guided by this valuable combination of necessary drugs. The desire for food is once more restored, and further, and what is most important, the capability of digesting it (especially the farinaceous portion) is increased.

The vehicle "BYNIN" is prepared from the finest Barley Malt by a special process, so that, although liquid, it contains as powerful diastasic properties as the ordinary viscid extract. Hence in cases where formerly Easton's Syrup was contra-indicated, owing to its tendency to produce indigestion, BYNIN AMARA is now successfully given, thereby supplying a most useful therapeutic agent.

Recent Medical Reports.

The British Medical Journal writes :—

"The preparation is very palatable, and there is no doubt it will be appreciated as a pleasant means of obtaining the tonic effects of Easton's Syrup combined with the diastasic and nutritive value of Extract of Malt."

The Lancet writes :—

"This excellent preparation is a distinct advance on Easton's Syrup . . . admirably adapted for the administration of one of the best tonic combinations known."

The Medical Press writes :—

". . . Not only is the taste improved, but, in addition to the well-known tonic properties of the formula we have an active digestive agent of farinaceous foods . . . a very ingenious and useful modification of an old and esteemed formula."

The Hospital Gazette writes :—

"The digestive properties of Bynin are so powerful that alone it is a valuable therapeutic agent; and it is obvious that Bynin Amara, containing as it does the above-named phosphates, is a tonic of exceptional potency and value."

Put up in bottles at (retail) 2/6 and 4/6 each.

Allen & Hanburys'

"Perfected" Cod-Liver Oil

IS prepared at their own factories in Lofoden and Söndmör, in Norway, from absolutely fresh and selected livers of the **Cod-fish only**, all stale livers being rejected. In stormy weather the fishing boats are often delayed, the fish being landed in a state of partial decomposition. This, together with the fact that manufacturers are frequently not careful to use only Cod livers, results in the Oil being of varying composition and contaminated with bye-products nauseous to the taste, indigestible, and irritating to the stomach.

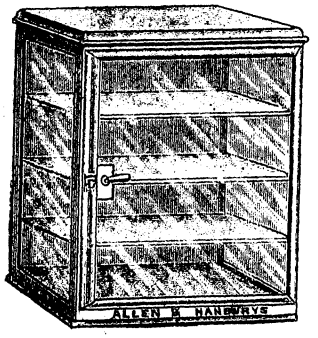
By the special processes employed the elimination of all nauseous oxidation products is effected without impairing in the smallest degree the invaluable nutritive and medicinal properties. By a very recent modification of our methods the "PERFECTED" Oil is now rendered freer from taste than at any period since its introduction to the Profession in 1879, when the British Medical Journal described it as having "almost the delicacy of Salad Oil," and the Lancet as being "as nearly free from taste as Cod-liver Oil can be."

Being easily borne and assimilated where ordinary Cod-liver Oil is refused, it is, for these and the above reasons, the most efficacious kind in use.

"It is a great boon to get such an Oil." —*The Practitioner.*

"No nauseous eructations follow after it is swallowed."—*Med. Press & Circular.*

In the "PERFECTED" Oil we have a food which can be easily digested, even in cases of Phthisical Dyspepsia, where Cod-liver Oil is specially indicated, yet cannot be borne.



ALLEN & HANBURYS desire to state, as emphatically as possible, that their "PERFECTED" Cod-liver Oil is *NEVER* supplied in bulk to be bottled by retail dealers, and that no Cod-liver Oil represented as being their "Perfected" is genuine unless sold in their original capsuled bottles and bearing their Signature in white across the label, and their Trade Mark—a Plough. Frequent misrepresentations have involved disappointment both to doctor and patient, and necessitated legal proceedings against the vendor.

THE

"Allenburys" Foods

FOR

TRADE MARK. A.D. 1715.

Infant Feeding

A PROGRESSIVE SERIES OF FOODS.

The Foods constituting the series described below are not interchangeable, but should be used in succession as indicated. Perfectly sterile in themselves, they are best given with the "Allenburys" Feeder, which is capable of easy and complete sterilization, thus presenting a physiologically accurate diet, free from all fear of contamination by the products of decomposition.

THE

"Allenburys" Milk Food No. 1

Affords, when prepared for use, a correct substitute for human milk. It is manufactured from fresh cow's milk, so modified as to present all the constituents of human milk in their true relative proportions. Being in a desiccated and sterilized form, it requires only the addition of *boiled* water to obtain a pure and sterile food suitable for infants during the first three months of life.

THE

"Allenburys" Milk Food No. 2

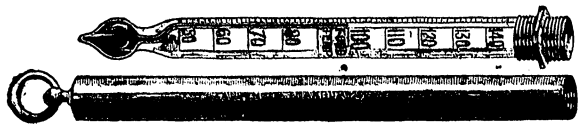
Is identical with No. 1, with the addition of small quantities of maltose, dextrine, and soluble phosphates derived from the digestion of whole meal with Malt Extract. These ingredients are a valuable adjunct to the increasing needs of digestion, yet the Food is readily and easily assimilated, there being no unconverted starch present. The No. 2 Food is designed for children between three and six months of age.

THE

"Allenburys" Malted Food, No. 3,

USUALLY KNOWN AS

Allen & Hanburys' Malted Infants' Food,



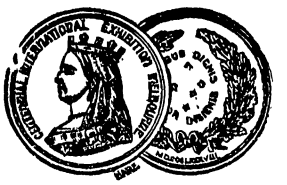
Is not a *milk*, but a purely *farinaceous* Food, prepared by improved methods after Baron von LIEBIG's formula. The basis is fine wheaten flour, which has been thoroughly cooked and partially digested by an active Malt Extract, so that a large proportion, but not all of the starch has been converted. It is particularly rich in soluble phosphates and albumenoids.

This Food should be given from six months and upwards. For the first month or so after the change of diet it is generally advisable, instead of using cow's milk, to employ the "ALLENBURYS" MILK FOOD No. 1 or No. 2 in preparing it. The demand on the child's digestive organs is less abrupt, and a humanized milk is used in place of the more indigestible cow's milk. This precaution is specially recommended in the case of delicate children.

The "Allenburys" Feeder.

This bottle has the nipple at one end and a valve-stopper at the other, so that, both being removed, it can readily be cleansed under the tap. The valve admits air behind the column of milk, thus avoiding the swallowing of air and the resulting wind-colic; while the rubber nipple is easily detached, and can be turned inside out. The bottle is graduated approximately in ounces. Price 1/- each.

The "Allenburys" Thermometer, in nickel case, as figured, is provided for determining the right temperature at which the Foods should be given, and for general Nursery use. 1/- each.



Allen & Hanburys Ltd., Plough Court, Lombard Street, London.

Infants' Food Manufactory: WARE MILLS, HERTFORDSHIRE.

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Liquor Pancreaticus (Benger).

For the preparation of peptonised or partially digested Milk and other articles of food.

Simple directions for use enclosed. In 4 oz., 8 oz., and 16 oz. Bottles.

The *British Medical Journal*, in an article on Benger's Preparations, says:—"Time and use have justified the claims put forward for these preparations."

The *London Medical Record* says:—"These are undoubtedly a great advance on any previous attempt in this direction. . . . The introduction of these preparations is a distinct advance in therapeutics."

The *Medical Times and Gazette* says:—"Benger's Preparations have deservedly a very high reputation, and are all largely used."

Liquor Pepticus (Benger).

An exceedingly active fluid pepsine, without disagreeable taste.

DOSE.—One or two teaspoonfuls with meals. In 4 oz., 8 oz., and 16 oz. Bottles.

Benger's Peptonised Beef Jelly.

A delicious quick restorative for Invalids and the Aged. In patent glass jars, no metallic contamination possible. Retail, 2s. each.

The Lancet says:—"It is a most valuable form of concentrated food."

The *London Medical Record* says:—"Invaluable for old people; also in convalescence from acute diseases."

A Physician writes:—"I feel I cannot express my gratitude to you sufficiently, as your Beef Jelly is the only thing my niece can retain, and it has certainly kept her alive for the last week."

Benger's Peptonised Chicken Jelly.

In similar glass jars. Retail, 2s. each.

The Lancet says:—"Mr. Benger's Preparations are now so well known that all we need say of the sample before us is—that it is excellent. It has a delicate chicken flavour."

The *Medical Press* says:—"Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in the treatment of the sick."

Benger's Preparations may be obtained through all Retail and Wholesale Houses and Shippers, or of the Manufacturers—

'Kepler' Malt Products

HAVE FROM THE FIRST BEEN RECOGNISED AS STANDARD PREPARATIONS OF UNDENIABLE EXCELLENCE AND RELIABILITY.

Burroughs Wellcome and Co., London and Sydney.

'Kepler' Malt Extract

IS the "best known and largest used Extract of Malt" *(The Lancet)*. It is the Malt Extract upon which the medical profession relies, and its unique reputation to-day is built upon the solid foundation of practical experience. Its perfection is not, therefore, theoretical only, but is established by actual clinical facts.

Small and large bottles, 1s. 8d. and 3s. per bottle.

[COPYRIGHT]

'Kepler' Solution

IS a molecular incorporation of the finest Norwegian Cod Liver Oil in 'Kepler' Malt Extract. It is readily assimilated, and no nausea or eructations follow its administration. Its palatability is such that even children relish it. "An ideal form for the administration of fat."—

British Medical Journal.

Small and large bottles, 1s. 8d. and 3s. per bottle.

TRADE MARK 'Tabloid' BRAND

Hypodermic Drugs

As to the superiority of 'Tabloid' Hypodermic Drugs over ready-made solutions there can be no question. 'Tabloid' Drugs are accurate in dosage, portable, and keep perfectly. Stock solutions are unreliable as to strength, bulky, inconvenient and frequently septic.

In hypodermic medication pure and non-irritating drugs are essential. The use of the word 'Tabloid' when ordering ensures the supply of such drugs. There are many imitations, which are inferior in every way.

'Tabloid' Hypodermic Drugs are instantly soluble in the syringe barrel. "They are quite free from objectionable and irritating salts."

—*BRITISH MEDICAL JOURNAL*

LIST.

'Tabloid' Hypodermic Products are put up in tubes containing 20, with the exception of those marked with an asterisk, which are in tubes of 12.

	Per tube
Aconitine Nitrate .. .. .. gr. 1/260	8d.
Apomorphine Hydrochloride gr. 1/15 and 1/10	6d.
Atropine Sulphate gr. 1/150, 1/100 and 1/60	6d.
Caffeine Sodio-salicylate .. .. gr. *1/2	8d.
Cocaine Hydrochloride gr. 1/10, 1/6, *1/4 and *1/2	6d.
Cocaine Compound— (*Weak, *Medium, and *Strong Anæsthetic)	8d.
Codeine Phosphate .. .. .. gr. 1/4	8d.
Cornutine Citrate .. .. .. gr. *1/60	8d.
Cotarnine Hydrochloride (Stypticin) gr. *1/4	8d.
Curare .. .. gr. 1/12	8d.
Digitalin .. .. gr. 1/100	6d.
Ergotinine Citrate .. gr. 1/200 and 1/100	8d.
Ergotinine Citrate .. .. .. *gr. 1/100) Strychnine Sulphate .. .. .. gr. 1/30)	8d.
Eserine Salicylate .. .. .. gr. 1/100	6d.
Eucaine Hydrochloride .. .. gr. *1/3	6d.
,, ,, ... gr. 1	1s.
Homatropine Hydrochloride .. .. gr. 1/250	8d.
Hydrarg. Perchlor. .. .. gr. 1/60 and 1/30	6d.
Hyoscine Hydrobromide gr. 1/200 and *1/75	6d.
Hyoscyamine Sulphate .. .. gr. *1/80	6d.
,, ,, ... gr. *1/20	8d.
Mercury Perchloride (*See Hydrarg. Perchlor.*)	
Morphine Bimeconate .. gr. 1/8, 1/6, 1/4 and 1/3	8d.
Morphine Hydrochloride .. gr. 1/6 and 1/4	6d.
Morphine Hydrochloride .. .. gr. *1/6) Atropine Sulphate .. .. .. gr. 1/70)	6d.
Morphine Sulphate gr. 1/8, 1/6, 1/4, 1/3 and *1/2	6d.
,, ,, ... gr. 1	8d.
Morphine Sulphate gr. 1/8 . 1/6 . 1/4 . 1/3) Atropine Sulphate gr. 1/200 . 1/180 . 1/150 . 1/120)	6d.
Morphine Sulphate .. .. gr. 1/3 . *1/2) Atropine Sulphate 1/60 . 1/100)	6d.
Nitroglycerin (Trinitrin) .. .. gr. 1/250	6d.
Physostigmine Salicylate .. .. gr. 1/100	6d.
Picrotoxin .. .. gr. 1/60	8d.
Pilocarpine Nitrate .. gr. 1/10, 1/6 and *1/3	8d.
,, ,, ... gr. *1/2	1s.
Potassium Permanganate .. .. gr. *2	6d.
Quinine Bihydrochloride .. .. gr. *1	6d.
,, ,, ... gr. *3	8d.
Quinine Hydrobromide .. .. gr. *1/2	8d.
Sparteine Sulphate .. .. .. gr. *1/2	8d.
Strophanthin .. .. gr. 1/500	8d.
Strychnine Nitrate .. .. gr. 1/15 and 1/10	8d.
Strychnine Sulph. gr. 1/150; 1/100; 1/60 and 1/30	6d.
Stypticin (Cotarnine Hydrochloride) gr. *1/4	8d.
Trinitrin (Nitroglycerin) .. .. gr. 1/250	6d.

The B. W. & Co. Patent Hypodermic Syringe.

With detachable nozzle, so that 'Tabloid' Hypodermic Products can be dissolved in the barrel. Capacity, min. 15 or 20. Two needles .. .. 7s.

A COURSE of mineral water treatment, either in England or abroad, has long been a recognized therapeutic measure in certain diseases. Its advantages are many and obvious, but it is, unfortunately, an impossible method of treatment for a large number of patients.

'TABLOID' Effervescent Artificial Mineral Water Salts contain in small bulk the essential constituents of the natural waters whose names they bear. By prescribing them in conjunction with a suitable dietary the physician is enabled to adopt the treatment carried out at British and Continental spas, and his patients have the advantage of being constantly under the care of their own medical adviser.

In addition to the therapeutic advantages which this series of 'Tabloid' Salts offers, their compactness and portability must be considered as important factors in securing regular and continuous treatment. One in a stated quantity of water forms a pleasant effervescing draught, which represents an equal volume of Carlsbad, Vichy, Kissingen or Seltzer water. The group is further extended by the inclusion of 'Tabloid' Effervescent Caffeine Citrate, Lithium Citrate, Magnesium Citrate (true), Magnesium Sulphate, Potassium Citrate, Sodium Phosphate, and Sodium Sulphate, particulars of which will be gladly sent on request. *(See also Wellcome's Medical Diary, 1899.)*

LIST OF

'TABLOID' MINERAL WATER SALTS

(Effervescent Artificial).

'TABLOID' CARLSBAD SALT.
'TABLOID' KISSINGEN SALT.

Why is *Vibrona* The Ideal Tonic ?

Because VIBRONA is a new and improved form of the **one incomparable Tonic** *CINCHONA*, whose claims rest on the accumulated experience of **more than two centuries.**

Because VIBRONA is pleasant to take, and **does not produce the headache, deafness, or other disagreeable sensations** caused by Quinine.

Because VIBRONA contains **all the tonic and aromatic principles** of Cinchona and is therefore **superior to Quinine alone.**

Because VIBRONA **is entirely free from Coca,** "the third scourge of humanity." (*vide British Medical Journal.*)

Because VIBRONA can be obtained either blended with a light dry Sherry, a rich Vintage Port, or a fine *Brut* Champagne.

Because For those who do not take Wine, VIBRONA MALT constitutes a Tonic nutritive of superlative value.

Because Overwhelming evidence that VIBRONA fulfils the claims made on its behalf is to be found in the spontaneous testimony of the **highest medical authorities.**

VIBRONA-SHERRY	*per bottle 2/9, per dozen 30/-*
VIBRONA-PORT	*per bottle 4/-., per dozen 45/-*
VIBRONA-CHAMPAGNE ...	*per doz. pints, 38/-, per case 72/-*
VIBRONA-MALT	*per bottle 2/9, double size 4/6.*

Superior to Cod Liver Oil, Tincture of Iron, or Peptone.

HOMMEL'S HÆMATOGEN

(Hæmoglobinum concentratum et Glycerinum purissimum [Imperial German Patent, No. 81391], agreeably flavoured).
Entirely free from Antiseptic Chemicals.

A BLOOD-FORMING TONIC, OF THE UTMOST VALUE

In General Debility, Anæmia, Chlorosis, Neurasthenia, Rickets, Scrofula, Weak Heart, Wasting Diseases of Children, Chronic Catarrh of the Stomach and Bowels, Loss of Appetite, Slow Convalescence after Fevers, and Over-Rapid Growth in Young Persons.

UNSURPASSED AS A MEDICINE FOR CHILDREN.

No Flavouring Required. Highly Relished by Patients of all Ages. Being a Fluid, it is very easy to take.
Gives Excellent Results in Rickets and Scrofula.
Far Superior to Cod Liver Oil, Iodide of Iron, and similar preparations.

"Using Hommel's Hæmatogen, I have had surprising success in cases of Anæmia, Debility, and Weak Digestion. In the treatment of Children, I have given up Cod Liver Oil, Chemical Preparations of Iron, and Sweet Wines, and instead of them I use only Hæmatogen, which has proved itself in my experience to be efficacious and prompt in its action. It has the further advantage of possessing an agreeable taste, **which makes it preferable to all other Hæmoglobin Preparations.**"
DR. NEUMANN, *Specialist for Children's Diseases, Munich.*

A POWERFUL RESTORATIVE IN DISEASES OF THE LUNGS.

"I consider Hommel's Hæmatogen to be a Food Product which has not as yet any equal, especially in the treatment of those who are recovering from illness."
DR. STEINHOFF, *Specialist for Diseases of the Lungs, Berlin.*

"I have employed Hommel's Hæmatogen in about 100 cases of Anæmia, Scrofula, Consumption, Tedious Convalescence, and Debility. **I have been so satisfied with it, that I do not now prescribe any other preparation of Iron.**"
DR. DEMME, *Berlin.*

Hommel's Hæmatogen may be given to Infants at the Breast, to Children of any Age, and to Adults continuously from year to year. Being a Natural Organic Product, it never causes any unpleasant symptoms whatever, nor does it ever produce vascular excitement or throbbing of the temples (orgasm), which are a necessary consequence of the long-continued use of Chemical Preparations of Iron.

GIVES AN APPETITE EVEN IN THE WORST CASES OF DISTASTE FOR FOOD.

Hommel's Hæmatogen contains (1) Perfectly Pure Hæmoglobin, (2) the whole of the salts which are found in Fresh Blood, and (3) the Highly Important Albuminous Constituents of the Serum in a Concentrated and Purified Form, without any Trace of Decomposition. It is not peptonised or predigested, for artificial digestion, whether it is accomplished by the action of acids and pepsin or by heat, is quite different from the natural process. It has been proved by Professor NEUMEISTER, of Jena, and Professor CAHN, of Strasbourg, that peptones, albumoses and peptonised preparations are not by any means absorbed directly, but are converted into albuminate before being absorbed. There is no doubt that artificial digestion brings about the decomposition of substances which are of the highest importance for building up the tissues of the body. This is strikingly shown by the great success of Hommel's Hæmatogen, in cases of Rickets, Scrofula, Wasting Diseases of Childhood, &c., in which not only Peptonised Preparations, but Cod Liver Oil, Iodide of Iron, &c., had been employed without any benefit.

We shall be happy to forward **Samples and Literature** *of Hommel's Hæmatogen, gratis and carriage paid, to Medical Practitioners who may wish to give it a trial.*

Kept in Stock by all Pharmaceutical Chemists. Price of Original 9-ounce Bottle **4s.**

Dose for young Infants, Half a Tea-spoonful, or one Tea-spoonful, twice a day in Milk, of the proper heat for drinking. For **Children,** One Table-spoonful, either pure or mixed with any convenient liquid. For **Adults,** One or Two Table-spoonfuls twice a day **before** food, so as to secure the full benefit of its powerful appetising effect.

NICOLAY & CO., 36 and 36a, St. Andrew's Hill, London, E.C.

Always Trustworthy.

IT has been proven by clinical tests that **BROMIDIA** is the best and safest hypnotic yet known to the Profession.

It is always of the same strength and, hence, can always be relied upon to produce the same results under the same conditions.

It is so well known and so well liked by the Profession everywhere that it can be obtained in almost every drug store in every country in the world.

Avoid substitution. The doctor should always take special care to get the genuine, which is only made by BATTLE. Substitutes not only injure the well deserved reputation of **BROMIDIA**, and the Chemical House of BATTLE, but it also affects the reputation of the doctor and is often harmful to the patient.

DOSE:—One-half to one fluid drachm, repeated as indicated.

BATTLE & CO. (Chemists Corporation),
ST. LOUIS, MO., U.S.A.

A Sample Bottle of BROMIDIA and Pamphlet will be forwarded free of charge to Medical Men on application to

ROBERTS & CO., 76, New Bond Street, London
GENERAL DEPOT FOR GREAT BRITAIN.

ANTI-DIPHTHERITIC SERUM.

GENUINE. RELIABLE. EXTRA POTENT.

Submitted for examination in the Laboratories of the Royal Colleges of Physicians (London), and Surgeons (England), and after being thoroughly tested, certified as to Antitoxin Unit Potency, freedom from micro-organisms, and from excessive amount of antiseptic.

Supplied in hermetically sealed glass bulbs, in potencies ranging from 500 to 750 Antitoxin Units per c c. in the following doses :—

No. 1,	containing	500	units*	in	about	1	c c.	or less.
2,	„	1000	„	„		2	„	„
3,	„	1500	„	„		3	„	„
4,	„	2000	„	„		4	„	„
5,	„	3000	„	„		5	„	„
6,	„	4000	„	„		7	„	„
7,	„	5000	„	„		9	„	„
8,	„	6000	„	„		10	„	„

ACCORDING TO POTENCY.

* Plus 25 per cent. excess not charged for.

We make a uniform charge of 6d. per 100 units.

POTENCY.—750 Units in the c c., thus, for the first time, commercially, putting it in the physician's power to administer the high number of Units now prescribed. The Serum will retain its *potency* for months.

QUALITY.—The only Serum on the market certified by an independent authority.

We also supply:—

ANTI-STREPTOCOCCIC SERUM in oz. cases (3 bulbs) ... ... per oz. **12s.**
For Puerperal Fever, Erysipelas, Scarlatina, and Streptococcus Diseases generally.

ANTI-TETANIC SERUM, Liquid, in oz. cases (3 bulbs) ... ... per oz. **20s.**

„ „ **dry,** equal to 1 oz. liquid ... ...per vial **20s.**

ANTI-TUBERCLE „ in oz. vials ... ... per oz. **12s.**

COLEY'S MIXTURE OF ERYSIPELAS AND PRODIGIOSUS TOXINS, in oz vials ... ... per oz. **12s.**
For the Treatment of Inoperable Malignant Tumours.

TUBERCULIN (Concentrated for Veterinary Use) in vials containing four doses ... ...per vial **3s.**
The only reliable agent for detecting Tuberculosis in Cattle and other animals.

SERUM SYRINGES.

No. 1. Complete, with four needles, 13s, 6d. | No. 2. Complete, with three needles, 12s.

JOSEPH TURNER & CO.'S
NEW SYNTHETIC REMEDIES.

SYNTHESIZED and MANUFACTURED in ENGLAND.

PIPERIDINE TARTRATE. The New Uric Acid Solvent.

Piperidine possesses uric acid solvent powers greatly superior to any other known substance, and, in combination with tartaric acid, forms a pleasant salt, which may be taken in 5 to 15 gr. doses in all wines, mineral waters, &c., at or before meals.

(See THE LANCET, July 23th, 1898; BRITISH MEDICAL JOURNAL, Feb. 27th, 1897; CENTRALBLATT DER PHYSIOLOGIE, Bd. iii., p. 434.)

GUAIPEROL (Guaiacolate of Piperidine).

This **REMEDY for PHTHISIS**, which combines the antiseptic properties of Guaiacol with the vascular tonic action of Piperidine, has been tried with considerable success at the London and other Chest Hospitals. It has not the irritant properties of Guaiacol, and possesses many advantages over the latter substance and preparations of the same now on the market. DOSE: from 10 gr. twice a day, preferably in cachets, after meals.

(See BRITISH MEDICAL JOURNAL, January 16th, 1897, and July 16th, 1898, &c.)

ERYTHROL TETRA NITRATE (Turner).
The New Vaso Dilator.

The difference between the action of Erythrol Tetra Nitrate and other vaso dilators consists mainly in the fact that the vaso dilatation produced from it is of a *much more permanent* nature, the administration of gr. i. by the mouth causing a reduction in arterial tension lasting for more than five hours.

(See BRADSHAW LECTURE, 1896; CROONIAN LECTURE, 1896; BRITISH MEDICAL JOURNAL, April 10th, 1897, January 1st, 1898, and January 8th, 1898, &c.)

SOLE PATENTEES & MANUFACTURERS, from whom Samples and Literature may be obtained:—

Re PHENACETINE.

IMPORTANT WARNING to MEDICAL MEN.

As discoverers and original makers of this **safe and valuable antipyretic**, we consider it to be our duty to **warn** the Medical Profession that an adulterated substance is now on the market, and is being sold as genuine Phenacetine. (*Vide* current Chemical and Pharmaceutical periodicals.) Our name is so well known in connexion with this product, that, for our reputation's sake, we are compelled to issue this notice.

Medical Men can protect themselves and their patients, and can rely upon obtaining a thoroughly pure product by adding the name BAYER when prescribing Phenacetine.

PHENACETINE-BAYER

is the pure and original product: the name is a guarantee of purity. Phenacetine-Bayer is put up in 4, 5, 8, and 16 grain Tablets, as well as in the Powder and Crystal form.

Samples and Literature can be obtained on application to the Wholesale Depots for all Bayer's Pharmaceutical Specialties—

ELBERFELD FARBEN FABRIKEN CO., Ld., 19, St. Dunstan's Hill, LONDON, E.C.

Also at MANCHESTER, GLASGOW and BRADFORD.

A Wide Field.

To name the affections in which the Thyroid treatment has been tried would necessitate the enumeration of the whole list of pathological conditions.

It is a specific of the first importance in Myxœdema, Cretinism, simple Goitre, and Obesity. It is of great value in Acute and Chronic Melancholia and Acute Delirium. The results following its employment in Psoriasis, Scleroderma, Eczema, Tetany, certain phases of Insanity, and in retarded development of children, have been such as to warrant further experiment.

Armour's Desiccated Thyroids and Thyroid Tablets are carefully made from selected material and may be depended upon in all cases where the Thyroid treatment is indicated.

Samples and Descriptive Matter forwarded to Physicians interested on application to

CELERINA.

W. P. England, M. D., White Pine, Pa., says: I have used Celerina and am pleased to say that in all cases of nervous prostration, such as follows the use of alcohol, and for all cases of nervous debility, I find it without an equal. After the experience I have had with it I do not hesitate in recommending it to the profession as one of our best nerve tonics.

The action of Celerina on the brain and nervous system is that of an exhilarant and slight narcotic, relieving depressions and lessens irritable nerve conditions. In cases of organic and functional lesions of the heart, an increased steadiness of pulse-beat and diminution of pulse irritation is apparent.

A. J. Wesco, M. D., Seven Mile, O., says: I have tested Celerina and got good results. Man, aged sixty-five years, mechanic, habits very intemperate, will spree for weeks, came to me with nervous system in bad fix; could not eat or sleep. Gave him eight ounces Celerina, teaspoonful three times a day, which placed him on his feet again, and for that I think it par excellence.

Convulsions may frequently be cut short, like magic, by teaspoonful doses of Celerina repeated at short intervals. The nausea as an after effect of chloroform or other narcosis, may generally be controlled in the same manner.

T. J. Haile, M. D., Atlanta, Ga., says: Celerina has always acted finely in all cases where I have tried it, especially in those troublesome cases of hysteria, nervous depression and feebleness, and prostration resulting from alcoholic excess. Have found its effects very exhilarating and nourishing. In fact it is my main dependence in all nervous diseases.

The psychological depressions and neuralgias, so common in the period following a debauch, are lessened or disappear altogether by the use of Celerina.

J. B. Johnson, M. D., 920 N St., Washington, D. C., says: I used Celerina not only as a nervine and tonic, but also found it most excellent, in two drachm doses, in sobering persons who were made drunk by alcoholic drink, and such patients informed me that they were greatly assisted in recovering from a spree by the use of Celerina.

After the removal of alcohol, Celerina, given in doses of from one-half to one ounce every four hours, is speedily followed by the most characteristic symptoms of improvement.

Dr. B——, Whitley, Northumberland, England, says: I have found Celerina valuable as a nerve stimulant and restorative in a patient suffering from the effects of a severe drinking bout.

RIO CHEMICAL CO., St. Louis, Mo., U.S.A.

THE ABOVE PREPARATION IS PREPARED EXCLUSIVELY FOR THE PRESCRIPTIONS OF MEDICAL MEN. A SAMPLE WILL BE SENT FREE TO ANY MEDICAL MAN WHO DESIRES TO TEST IT, ON APPLICATION TO

RIO CHEMICAL CO., 36, Basinghall Street, E.C.

Duotal (Guaiacol Carbonate)
Creosotal (Creosote Carbonate)

For the Treatment of Tuberculosis, Chronic Intestinal Diseases, Enteric Fever, &c.

While possessing the purely curative action of beechwood creosote and guaiacol, Creosotal and Guaiacol Carbonate have absolutely no caustic effects. The tolerance displayed to these two carbonates depends on:

1. The absence of caustic and poisonous properties.
2. The absence of the intensely nauseous creosote taste and odour.
3. The fact that resorption takes place, not in the stomach, but in the intestines.

Guaiacol Carbonate and Creosotal act *continuously and mildly* on the digestive tract and the entire organism. This continuous absorption is a necessary condition for their therapeutic effect. Disassociation takes place slowly in the intestines; and, unlike other antiseptics, the *Carbonates are distributed over the whole duodenum, jejunum, and ileum.* While creosote and liquid guaiacol injure the digestive tract by causing chronic inflammation of its mucous membrane, Creosote Carbonate and Guaiacol Carbonate tone it up and stimulate it.

We beg to draw attention to Von Heyden's Preparations:—

ACTOL (Crede's Lactate of Silver.)
ANTISEPTIC CREDE (Citrate of Silver).
APOLYSIN.
GUAIACOL, crist and liquid.
ORPHOL (Betanaphtol-Bismuth.)
XEROFORM (Tribromphenol-Bismuth.)
SOLVEOL.
UNGUENTUM CREDE (Ointment of soluble metallic silver).

FREE SAMPLES and LITERATURE are sent on application to

St. RAPHAËL-QUINQUINA TONIC WINE

THE LANCET MAY 28TH 1898 WRITES "UNDOUBTEDLY OF TONIC VALUE"

TAKE A GLASS BEFORE MEALS

ST. RAPHAËL QUINQUINA is a TONIC WINE of the greatest value and of delicious flavour. For Loss of Appetite, Anæmic Conditions, and Nervous Depression it is the most wonderful tonic ever brought before the public. In Paris it has by far the largest sale of any tonic wine, and is in great demand as an appetiser. For ordinary beverage purposes, mixed with mineral water, it is most refreshing, agreeable and stimulating.

The attention of the Medical Profession is invited with every confidence and Samples forwarded free on application.

Sole Agents: BOWEN & McKECHNIE, Cross Street, Finsbury, E.C.,
TO WHOM ALL COMMUNICATIONS SHOULD BE ADDRESSED.

HOOKER'S MILK WINE

"VILNAC" Registered Trade Mark. (PATENTED)

Of extreme utility in cases of—

DYSPEPSIA, ANÆMIA, DEBILITY TUBERCULOSIS, PHTHISIS, INSOMNIA, HEART WEAKNESS, TYPHOID & OTHER FEVERS, ALL WASTING DISEASES, MENTAL & PHYSICAL OVERWORK LOSS OF APPETITE, &c., &c.

A PEPTONIZED product of milk containing all the constituents of the original milk (except fat) in a completely digested form. It is of great medical value for use in the sick-room—for convalescents—for those suffering from dyspepsia, insomnia, nervous disorders, &c. Its value consists in the fact that the whole of the casein or curd of the milk is present in the Wine in the form of peptones, which are capable of being absorbed into the system **without digestive effort.** Whilst possessing all the valuable properties of a highly peptonized Milk, it takes the form of a sound and palatable Wine, of great use in all febrile disorders and cases of acute illness where milk, or milk and a stimulant, is essential and often difficult to administer. It is, in fact, a **powerful food stimulant** and tonic, and may be used successfully both in illness and convalescence. It is a most useful **appetizer** and aid to digestion under any circumstances, especially for the weak and aged. Many valuable testimonials have already been obtained from medical men and others who have tested and used the Wine.

A PHYSICIAN IN LARGE PRACTICE CERTIFIES:—"HOOKER'S MILK WINE is a valuable addition to the dietary of the sick room, and I have found it a powerful restorative and stimulant, not only in severe illness, but also in cases of nervous exhaustion induced by overwork, study, and other causes. It has also been used with marked and surprising success where no other food could be taken, and I have been struck with its value as an appetizer when taken shortly before a meal."

The MILK WINE is sold in wine quarts and pints. Prices, respectively, **4/6** *and* **2/6** *per bottle, and may be obtained through any Chemist, or from the Manufacturers:—*

THE MILK WINE CO., Ltd., 9, Arundel St., Strand, London, W.C.

FREE SAMPLES TO MEDICAL PRACTITIONERS ONLY will be sent on application. Included with each sample is a small bottle of Tannic Acid in solution. A simple experiment will then immediately demonstrate the Milk Peptones present in the Wine

CONTREXEVILLE

Be Careful to specify:
SOURCE DU **PAVILLON**

GOUT, GRAVEL, DIABETES, ARTHRITISM

(Diuretic, Tonic, Digestible)

The Contrexéville Mineral Water (Pavillon SPRING) is a diuretic and laxative, a tonic, a stimulant, and aid to digestion. — It acts upon the secret mechanism of nutrition, as is proved by its influence in checking the production of uric acid and glucose : it favourably modifies those morbid processus of biological chemistry which result in the accumulation of uric acid in the blood, inducing the phenomena of gout. — It facilitates the elimination of urinary deposits, by contracting the ducts containing them and increasing the quantity of liquid by which these vessels are flushed. — It assists the cicatrization of the inflamed mucus of the urinary organs, and helps to restore the normal acidity of the urine; facilitates the flow of the bile, by causing contraction of the biliary ducts and the expulsion of calculi: and is invaluable in the treatment of congestion of the liver.

Samples free to Members of the Medical Profession on application to INGRAM & ROYLE, *East Paul's Wharf, 26, Up. Thames St., E.C.*

MOUNTJOY BREWERY, LTD.

(Late FINDLATER & CO.),

RUSSELL STREET, DUBLIN.

NOURISHING STOUT.

THE attention of Medical Men is respectfully called to the value of this finest of Malt drinks as a valuable Tonic Restorative. Numerous Unsolicited Testimonials have been received by our Bottlers all over England.

SAMPLES will be sent direct from the BREWERY, Carriage Paid, with name of nearest Bottlers, on application.

ANALYTICAL RECORD FROM "THE LANCET."

"CROWN STOUT.—MOUNTJOY BREWERY, RUSSELL STREET, DUBLIN.

"The nourishing qualities of Stout are due mainly to a comparatively high proportion of Malt extractions, which, consisting principally of maltose and dextrine, offer little task to the digestive organs. The sample before us is marked by an excellent proportion of these extractions, while, at the same time, the alcoholic strength is by no means excessive.

"The results of analysis were as follows: Malt extractions, 9·0 per cent.; mineral matter, 1·38 per cent.; alcohol—by weight 4·62 per cent., by volume 5·78 per cent.; equal to proof spirit 10·13 per cent. The mineral matters consisted almost entirely of soluble potassium phosphate. The Stout was in good condition, ripe, yet free from undue acidity, and possessed a characteristic malty flavour."

SIR CHARLES CAMERON'S ANALYSIS.

"DUBLIN.

"I have analysed a specimen of **Nourishing Dublin Stout**, submitted to me for that purpose by **The Mountjoy Brewery, Dublin.** I have never examined a specimen of Porter in which the solid or nutritive constituents were so abundant as in the case of this Stout. It contains **Ten Per Cent.** of its weight of solid matter, or nearly the amount of solids contained in milk. Its flavour is good, and it is **Remarkably Free from Acidity.**

"CHARLES A. CAMERON,

"*Professor of Chemistry, College of Surgeons, Dublin.*"

PROFESSOR TICHBORNE'S ANALYSIS.

"DUBLIN.

"I have examined and analysed for several years the Stouts brewed by **The Mountjoy Brewery**—viz., **Single, Extra,** and their speciality known as **Nourishing** or **Crown** Stout. The gravities of all these Stouts are very high, as proved by my analysis. **The Crown** or **Nourishing** Stout gave me one of the highest gravities I have ever seen in Stout. They are all of first-class quality. **The Nourishing** Stout being exceptionally fine, and owing to its **strength and purity,** is a most valuable food for **Invalids.** They are all brewed from **Malt** and **Hops only,** the water used being the best brewing water the City of Dublin affords.

"CHARLES R. C. TICHBORNE,

"*Professor of Chemistry, Dublin.*"

WHOOPING COUGH instantly relieved by using

VAPO-CRESOLENE

Vapo-Cresolene.

CHILDREN, by simply breathing the Vapour of CRESOLENE, obtain extraordinary relief in Whooping Cough, and the disorder is rapidly put an end to, generally in a few days. It is a perfectly safe remedy, and will not harm the youngest child. CRESOLENE is most valuable in ASTHMA, CATARRH, SCARLET FEVER, DIPHTHERIA, HAY FEVER, &c., and is claimed to be the most powerful antiseptic and disinfectant at present known.

Vapouriser, with Lamp and 2-oz. Bottle of Cresolene, complete, 6s. Obtainable through any Chemist. The Cresolene can be had separately in Bottles, at 1s. 1½d. and 2s.

Sole Agents for Europe—ALLEN & HANBURYS Ltd., Plough Court, Lombard Street, London.

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION.

HÆMORRHOIDS, BILE,
CEREBRAL CONGESTION, HEADACHE,
LOSS OF APPETITE,
INTESTINAL OBSTRUCTIONS, &c.

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BELIN and TARDIEU, who prescribe it constantly for the above complaints, and with most marked success.

Wholesale—London: E. GRILLON, 47, Southwark Street, London, S.E.
Sold by all Chemists and Druggists, 2s. 6d. a box, stamp included.

"LIQ. SANTAL FLAV. c. BUCHU ET CUBEBÆ"

(HEWLETT'S).

THE ORIGINAL PREPARATION.

Report of "THE PRACTITIONER":—

"Experience has shown this preparation to possess *the same efficacy as Santal Oil itself.* It mixes perfectly with water, and has a taste by no means disagreeable, in which particular it contrasts very favourably with the ordinary mixture it is intended to replace."

To ensure obtaining this preparation, please write: "Liq. Santal Flav. c. Buchu et Cubebæ (Hewlett's)."

Price 10s. 6d. per lb. packed, for dispensing only, in 10, 22, 40, and 90-oz. Bottles.

INTRODUCED AND PREPARED ONLY BY

C. J. HEWLETT & SON, Wholesale & Export Druggists,
40, 41, & 42, CHARLOTTE STREET, LONDON, E.C.

MISTURA CERII COMPOSITA.

MACKEY'S ORIGINAL PREPARATION.

TONIC, STOMACHIC, AND ANTI-DYSPEPTIC.

Composition—Cerii Am. Citrat., Tinct. Nux Vomica, Acid Hydrocyanic, P.B., and Spt. Chloroform.

This preparation has been made in accordance with the prescription of a most eminent Physician, and it is found that the Cerium and the other sedatives are presented in a form which produces the highest beneficial action which the ingredients are capable of giving.

It has been much used, with marked advantage, in Chronic Intestinal Eruption and in irritable Dyspepsia, attended with Gastrodynia, Pyrosis, and Chronic Vomiting. In obstinate Vomiting, especially in the Vomiting of Pregnancy, Mist. Cerii Co. seldom fails.

In Bottles, 2s. 9d., 5s., and 9s. each.

INTRODUCED AND PREPARED ONLY BY

VIN MARIANI

(MARIANI WINE.)

More than 6000 physicians have certified to the immense sustaining, recuperative, and nourishing properties of this wine, which is indicated in cases of

OVER-EXERTION,
NEURASTHENIA,
NERVOUS DEPRESSION
SLEEPLESSNESS,
NERVOUS DEBILITY
CONVALESCENCE,
VOCAL FATIGUE.

Purchasers should insist on getting Mariani Wine and accept no substitute.

Price 4s. per bottle; or 45s. per dozen.

Sample bottles free to the Medical Profession.

CRYSTALLIZED DIGITALINE Nativelle.

The Paris Academy of Medicine awarded a prize of 6000 francs to M. Nativelle for the discovery of CRYSTALLISED Digitaline.

CRYSTALLISED DIGITALINE (NATIVELLE) is a definite substance that can always be relied on and administered with exactitude. After a few doses the pulsations of the heart become slower, more regular, and more energetic.

Prepared in Bottles of 50 granules, each granule containing a 240th grain (¼-milligramme). A Sample, with Opinions of the Press and Medical Profession, free by post from WILCOX & CO., 83, Mortimer-street, London.

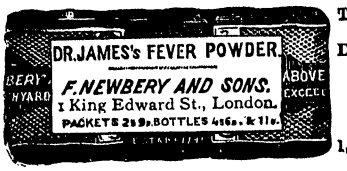
CIGARES DE JOY

ASTHMA
CHRONIC BRONCHITIS

One of these Cigarettes gives IMMEDIATE RELIEF in cases of ASTHMA, CHRONIC BRONCHITIS, HAY FEVER, COUGH, and SHORTNESS OF BREATH, and their daily use effects a COMPLETE CURE. The contraction of the air tubes, which causes tightness of chest and difficulty of breathing, is at once lessened by inhaling the medicated smoke of the Cigarette; a free expectoration ensues, and the breathing organs resume their natural action. Persons who suffer at night with COUGHING, PHLEGM, and SHORT BREATH find them invaluable, as they instantly check the spasm, promote sleep, and allow the patient to pass a good night.

Price 2s. 6d. per box of 35 Cigarettes, from WILCOX & CO., 83, Mortimer-street, London, W.

Sample boxes free to the Medical Profession.



WILCOX & CO.'S DESICCATED EXTRACT OF MALT

A Concentrated, Nutritive, and Digestive Food for INVALIDS and CHILDREN.

This preparation embodies all the beneficial properties of the most carefully prepared semi-fluid extracts, and possesses the additional advantages of greater richness in DIASTASE and the impossibility of fermentation. This powder may be eaten between bread-and-butter or dissolved in liquid, and, being a natural solvent of farinaceous material, it is strongly recommended as an adjunct to Children's Food and for ladies whilst nursing.

Prepared only by WILCOX & CO., 83, Mortimer-street, London, and put up in large bottles at 2s. 6d. each. Messrs. W. & Co., will be pleased to forward a sample to any of the Medical Profession.

PULVIS JACOBI VER., NEWBERY.

This is the ORIGINAL ARTICLE from the recipe in DR. JAMES'S OWN HANDWRITING in the possession of MESSRS. NEWBERY.

Prices for Dispensing: 1 oz., 9s.; ½ oz., 3s. 4d. 1, King Edward-st., Newgate-street, E.C.; 125 years in St. Paul's Churchyard

THE BRIDGE OF HEALTH IS

FERRU-COCOA

IT ENRICHES THE BLOOD

Prepared under MEDICAL INSTRUCTION from Purest COCOA, KOLA NUT, MALT and the FERRUGINOUS or IRON BEARING ELEMENTS of FOOD.

A DELICIOUS, REFRESHING, AND SUSTAINING BEVERAGE.

Owing to the Ferruginous Elements contained in it, Ferru-Cocoa largely assists in the formation of Hæmoglobin, or red colouring matter in the Blood, thereby being of the greatest value to children and invalids in aiding to build up a sound, healthy constitution.

FERRU-COCOA is Muscle-forming, Force-producing, and ENRICHES THE BLOOD.

The "LANCET" says:—"Normally Cocoa contains NO iron, and its addition in an organic form in the preparation before us (Ferru-Cocoa) is a step of some importance."

The "HOSPITAL" says:—"Ferru-Cocoa is a preparation of Cocoa from which a large proportion of the natural fat of the Cocoa-bean has been removed, thereby rendering the preparation more digestible. For all who require a larger amount of ferruginous material than is provided in ordinary articles of diet, this preparation is likely to be useful."

Strongly recommended by the highest medical experts and analysts as the most valuable Blood-forming and Blood-enriching FOOD BEVERAGE known.

Packed in 6d., 9d., and 1/6 Tins of all Chemists and Grocers.

FREE SAMPLES SENT TO TRAINED NURSES AND MEDICAL MEN ON APPLICATION.

PAID IN CLAIMS ... ... ,, £10,000,000

All the Profits are Divided amongst the Assured; already divided, £5,400,000.

Endowment-Assurance Policies are issued, combining Life Assurance, at minimum cost, with provision for old age. The practical effect of these policies in the National Provident Institution is that the member's life is assured until he reaches the age agreed upon, and on his reaching that age the whole of the premiums paid are returned to him, and a considerable sum in addition, representing a by no means insignificant rate of interest on his payments. — No. 48, Gracechurch-street, London, E.C.

SMEDLEY'S, MATLOCK.

HYDROPATHIC ESTABLISHMENT

STATION—MATLOCK BRIDGE.

THE RADIANT HEAT BATH.

A new installation of these Baths has just been added. The local application of superheated dry air has produced undoubted benefit in Chronic Rheumatism, Gout, Rheumatoid Arthritis, Stiff and Painful Joints, Neuralgias, Lumbago, Sciatica, Sprains, &c.

The heat being produced by ELECTRICITY, there is no vitiation of the atmosphere by products of combustion, and the apparatus is under perfect control, being provided with a regulator by means of which the temperature can be graduated throughout a range of over 400° F.

These local baths are specially useful in cases where the patient is enfeebled or crippled, or from any cause unfit for the application of the ordinary Turkish or other form of hot-air bath.

The baths are given under medical direction only.

Terms and Prospectus on application to the Manager.

St. Andrew's Hospital for Mental

DISEASES,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President—The Right Honble. the EARL SPENCER, K.G.

The Institution is pleasantly situated in a healthy locality, one mile from the London and North-Western or Midland lines, and one and a half hour only from London.

It is surrounded by more than 100 acres of pleasure grounds.

Great care is exercised in the classification of the Patients according to their habits and different degrees of mental aberration, so that those who are quiet or convalescent may not associate with those whose minds are more affected.

Ample means of occupation and amusement are provided, including Cricket, Croquet, Lawn Tennis, and Archery. There are also Billiard Rooms, and a large Recreation Hall and Theatre.

The terms vary from 25s. to £4 4s. week, according to the requirements of the case.

Patients paying higher rates can have Special Attendants, Horses, and Carriages; and Private Rooms in the hospital; or in detached villas in the grounds of the hospital; or at Moulton Park, a branch establishment, two miles from the hospital.

There is also a Seaside House, to which Patients may be sent.

For further information apply to the Medical Superintendent.

Warneford Asylum, Oxford.—This

Asylum, for the care and treatment of the Insane of both sexes of the Middle and Upper Classes, is pleasantly situated on Headlington-hill, near Oxford, and has been recently enlarged. The grounds are extensive, and cricket, tennis, billiards, dances, and other amusements are amply provided. There are now vacancies for patients at moderate charges. Voluntary patients can also be received.—For particulars apply to the Medical Superintendent, Dr. NEIL.

NERVOUS & MENTAL AFFECTIONS.

The Grove, Catton, near Norwich.—

A quiet **HOME** for the **Special Treatment** of a limited number of **Ladies** suffering from **Nervous** and **Mental Affections.** The house stands in beautiful grounds of about ten acres in extent, is situated a mile and a half from the **City** of **Norwich**, and contains the most modern requirements and comforts.

Carriage drives and **amusements** of all kinds are provided for patients. **Boarders** are also received **without certificates.**

All communications treated as confidential.

List of terms (which are moderate) and references gratis on application.

Telegraphic Address: "Interjoin, London."

MEDICAL PARTNERSHIP AND CONVEYANCING AGENCY,
1, ADAM-STREET, ADELPHI, W.C.

The SALE of PRACTICES and PARTNERSHIPS NEGOTIATED.

Trustworthy LOCUM TENENS and ASSISTANTS can be had at a few hours' notice.

N.B.—No charge made to Purchasers.

Notice.—Mr. J. C. Needes, with an experience of over a quarter of a century, is in an exceptional position to give intending purchasers independent information concerning most PRACTICES and PARTNERSHIPS. Those investments in the following List marked with an asterisk are well known to him, having been purchased through his Office by the present Incumbents years ago, and in many other cases an introduction can be given to gentlemen who have taken charge of the Practices during the absence of the Incumbents.

WEST.—A PRACTICE of many years' standing situated in a prosperous Seaport Town, over 20,000 inhabitants, is for negotiation. Held by vendor twenty years. The income is between £800 and £1000 per annum, including valuable transferable appointments. Practice easily worked with one horse. A good introduction given.

SOUTH.—Easily-worked PRACTICE, about £500 a year, in a small Country Town within seventy miles of London. Railway station in place. Capable of increase. Commodious house with land attached, held at a moderate rental. Further particulars on application.

CASH PRACTICE without residence. Established twenty years. Receipts over £12 per week. An assistant is kept and the incumbent resides at a distance. The Practice which is steadily increasing, is situated on the borders of the E.C. and N. postal districts.

WEST LONDON.—A Lucrative PRACTICE (held nearly twenty years by the present incumbent), yielding £1400 per annum, of which about £18 per week is received in ready cash at a separate surgery. The private house (rent £70) is situated in a residential locality and is connected with the surgery by telephone. Premium £1550.

PARTNERSHIP, LONDON.—The third share of a good-class cash PRACTICE in the S.E. District can be secured by an active gentleman. Receipts £2000 per annum. Dispenser and carriage kept. About 150 cases of midwifery yearly at 1 to 2 guineas. The ingoing partner's income will be guaranteed.

COLONIAL.—In a residential suburb of one of the principal cities in Australia a Non-dispensing PRACTICE averaging for the last three years over £1200 per annum, including appointments £350. Held by vendor twelve years. The connexion (which includes the best people in the place) is principally confined to a radius of two miles. The opposition is not formidable. Detached house (half a mile from the sea and standing in its own grounds), containing thirteen rooms, bath-room, &c.; gas and water laid on; rent £110 a year or can be purchased if wished, as it is vendor's freehold. The climate is cool and healthy. Educational advantages in the place for boys and girls. Premium £800. A good introduction and London references given.

SOUTH LONDON.—A very old-established PRACTICE yielding upwards of £500 per annum. Clubs, &c., £80. Horse no kept. Visits 2s. 6d. About thirty cases of Midwifery early. Commodious corner Residence (3 sitting-rooms, 5 bedrooms, bath-room, &c.), with garden attached. Rent £60. Premium £650, to include drugs. An efficient introduction.

OVER £1500 A YEAR.—SOUTH.—The Succession to a Good-class PRACTICE in a Cathedral City in the South of England can be negotiated for by a Gentleman of age and experience. Midwifery has been refused. Large family residence; rent under £100 per annum. Premium £2000.

SEASIDE TOWN.—SOUTH.—An increasing middle-class PRACTICE, the cash receipts of which last year were between £700 and £800. 30 to 40 cases of Midwifery yearly at one guinea upwards. Neither horse nor assistant is kept. House rent moderate. Premium £350.

Apply to J. C. NEEDES, 1, Adam-street, Adelphi, W.C.

Required. — A Gentleman with private means is prepared to pay a liberal price for a Country PRACTICE in the West of England, where there are opportunities for hunting and sport generally. Income from £400 to £800 a year. Good house essential. Particulars will be received in confidence by J. C. Needes, 1, Adam-street, Adelphi, W.C.

Locum Tenens and Temporary ASSISTANTS.—Practitioners requiring the above can immediately obtain thoroughly reliable qualified Gentlemen upon application to 1, Adam-street, Adelphi, W.C. Every Gentleman engaged by the Office in either of the above capacities is personally known to Mr. J. C. Needes. An office fee of half a guinea is payable by the Principal.

Telegraphic Address, "Acquirement, London."

THE SCHOLASTIC, CLERICAL, & MEDICAL ASSOCIATION, LTD.

MEDICAL DEPARTMENT.

This Association was established in 1889 as a Limited Liability Company under the direction of professional men, its object being the creation of a RESPONSIBLE and THOROUGHLY TRUSTWORTHY Agency. The Medical Department has met with so great success that it has been found necessary for one of the Managing Directors (Mr. G. B. Stocker) to devote his whole attention thereto; and he has the assistance of an experienced Medical Accountant and a large staff of clerks. Further, a Board composed entirely of gentlemen of high standing in the Medical Profession has been appointed, and to them matters of dispute and complaint are referred.

The Association undertakes the SALE of PRACTICES and PARTNERSHIPS; the Introduction of LOCUM TENENS and ASSISTANTS; MEDICAL ACCOUNTANCY (by a duly qualified Medical Accountant); INVESTIGATION and VALUATION of Practices, &c.; POSTING BOOKS and sending out Bills, &c., &c.

A Pamphlet relating to the Medical Department, with the names of the "Directors" and "The Medical Advising Board," and terms, will be sent on application to—MR. G. B. STOCKER,* MANAGING DIRECTOR, 8, LANCASTER PLACE, STRAND, W.C.

Telegraphic Address—"Triform, London." Telephone No. 1854 (Gerrard).

FOR SALE.

(1) FOR TRANSFER.—A PRACTICE in a beautiful part of the country (seaside). Charming and agreeable climate. Receipts £700 (including appointment of about £50 just obtained), with scope for considerable increase. Very attractive house and grounds. Educational facilities. Good golf and other sport. Six months' introduction. Premium £1400.

(2) YORKSHIRE.—WEST RIDING.—An old-established PRACTICE in a rapidly increasing Town. Cash receipts average £867 per annum. Visiting fees 2s. 6d. upwards. Very good house, with stabling and garden. Rent £117. Sport of all kinds. Six months' introduction. Premium £1200. The Practice can be worked by hiring only.

(3) SMALL PRIVATE ASYLUM. Within fifty miles of London. Premium £1000.

(4) HOME COUNTIES.—Old-established PRACTICE in a residential town, within easy access of London, estimated to be worth about £600 per annum. Visiting fees, 3s. 6d. to 10s. 6d. Would take a partner to live in the house for three years or so, and succeed to the whole.

(5) YORKS, WEST RIDING.—Old-established country PRACTICE of about £1500 per annum. Two horses. Good house, with tennis lawn and stabling. Rent £100. Twelve months' introduction. Premium £2250.

MEDICAL TRANSFER AND PARTNERSHIP.

32, Ludgate-hill.

Messrs. Orridge & Co., Medical

Transfer Agents, Referees, and Valuers, in offering their services to the Profession, have pleasure in referring to the fact that for ABOUT HALF A CENTURY the name of Mr. ORRIDGE has been known in the advertising columns of the leading medical journals, and that a very large proportion of the Medical Men throughout the kingdom have confided their interest in the adjustment of PARTNERSHIPS and TRANSFERS to their care.

Purchasers who will communicate (confidentially) the NATURE and EXTENT of their wishes regarding investment can be apprised of appropriate opportunities as they occur.

On occasion where ADVICE is required in forming a correct conclusion as to the worth or eligibility of a Practice, Messrs. ORRIDGE & Co. trust that their familiarity with the various contingencies that govern value will be found of considerable service to those by whom they are employed. N.B.—No charge is made to purchasers.

MEDICAL TRANSFER AGENCY (ESTAB. 1860),
168, EUSTON-ROAD, N.W.

Mr. Herbert Needes (son of the late

Mrs. Needes, and for more than ten years associated with her in the management of this old Agency) is still carrying on the Business, and will be glad to negotiate the Transfer of PRACTICES and PARTNERSHIPS on the usual terms. No connexion with any other office.

LOCUM TENENS.—Reliable Gentlemen always on the Books.

ASSISTANTS provided free of charge to Principals.

1. IMMEDIATE.—£200 accepted for a mixed-class SURGERY in the N. of London, returning £500 a year. Vendor has held possession over twelve years and is ordered abroad on account of his health. No dispensary fees. Rent £60. Must be taken up at once.
2. DEATH VACANCY.—WITHIN 50 MILES.—Entirely unopposed PRACTICE in a pretty country and held by the late owner 25 years. Receipts this year over £1000, including £240 from transferable appointments. A very efficient introduction can be given.
3. DERBYSHIRE.—In an attractive part of this favourite county a country PRACTICE returning between £450 to £500 a year offers for sale. Appointments £70. Nearest resident opposition 2½ miles. Convenient house, with bath-room, &c., rent £40. Price with three months' introduction, £600.
4. NORTH OF ENGLAND.—£700 to £800 per annum. General PRACTICE returning the above income and situate in a large town on the coast. Nearly half the returns derived from transferable appointments. Small but convenient house, rent £30. Six months' introduction. Price 1000 guineas.
5. EASY TERMS OF PURCHASE may be arranged in the matter of an increasing PRACTICE close to two large Yorkshire towns. Receipts for past twelve months £450. No horse required. Rent moderate. An immediate transfer is desired for reasons which will be satisfactorily explained.
6. HOME COUNTY PRACTICE in a rising town and returning about £800 a year, including £70 from appointments. Very little midwifery. Good scope for an active man. One horse required. Convenient detached house with garden and stabling. Rent £75. Price £1250.

Telegrams: "CURANDUS," LONDON.

M. D. Lond., aged 38, married, wishes

to purchase a good-class PRACTICE, or PARTNERSHIP with view to Succession, in pleasant Provincial town, or pretty and healthy country place. Good roomy house and garden essential. Income not less than £800. Advertiser has long experience in high-class practice, and is free to enter at once on a suitable thing. Ample capital.—Address, M.D., care of Messrs. Miller, Vardon and Miller, 12, Savile-row, London, W.

Graduate in Arts and Medicine

desires to purchase PARTNERSHIP in good-class Practice, preferably in South of England. Share £600 upwards. Ex-H.S. and Resident Medical Officer. Bachelor; thirty. Best references. Fullest investigation required.—Address, No. 1415, THE LANCET Office, 423, Strand, W.C.

NERSHIP in Town or Country; age thirty. Plenty of experience of all kinds of Practice. Income must be £500 and upwards.—Address, No. 1414, THE LANCET Office, 423, Strand, W.C.

Digitized by Google

Partnership or Nucleus of Practice wanted near London, West preferred, by young practitioner, M.B. London, D.P.H., &c.—Address, B. L. S, 202, Marylebone-road, N W

Wanted, in March, a Partnership, or Good-class PRACTICE, in a large residential town, income at least £500, by M D. Edin. of good social position, age thirty, of considerable surgical experience, excellent references, married. Gravel soil preferred.—No. 1409, THE LANCET Office 423, Strand, W.C.

South Coast.—A capital Nucleus will be transferred and short introduction given to anyone taking over lease of house and paying for fixtures, value £30. Satisfactory reason for leaving.—Address, No. 1408, THE LANCET Office, 423, Strand, W.C.

Death Vacancy.—West end of GLASGOW.—The PRACTICE of a Medical Gentleman, recently deceased, for Disposal. House could be occupied meantime with deceased's relatives.—Apply to Marshall and MacLachlan, 28, Renfield-street, Glasgow.

Practice for Sale.—Cheshire.— Average cash receipts for last five years £180. Four miles from Crewe. House, with stabling and garden, £19. Price £150.—Apply, Dr. Lightbody, Wybunbury, near Nantwich, Cheshire.

For immediate Disposal.—Small PRACTICE. Present receipts about £200 yearly, including transferable clubs and appointments. Plenty of scope for increase. Reason for sale ill-health. Suitable introduction given. Price to prompt purchaser £50, which includes drugs and book debts.—Address, No. 1416, THE LANCET Office, 423, Strand, W.C.

Yorkshire.—Village Nucleus now returning about £360, with capital prospect of increase. Easily worked with bicycle or one horse. Comfortable house, good garden, &c., at £20. Price £275, and small valuation.—Mr. Huish, 8, Fisher-street, Red Lion Square, W.C.

For Sale, Practice in South London, doing £360. Cash takings £3 weekly. Great scope for increase. Price to immediate purchaser £200, to include drugs, fixtures, and book debts.—Address, No. 1420, THE LANCET Office, 423, Strand, W.C.

South Coast.—For immediate Dis- posal owing to ill-health, an easily worked genuine PRACTICE, in growing neighbourhood, with great scope. Price inclusive, £200. Introduction to suit purchaser. Interview will give satisfaction.—Address, No. 1422, THE LANCET Office, 423, Strand, W.C.

London.—Rapidly developing Cash NUCLEUS in a thickly-populated part of the N. district. Consequent upon other engagements the attendance has been limited, and being non-residential, Midwifery and night calls have been refused. Good corner position. To an active successor devoting more time, and especially a resident, the opportunity is most favourable. Address "Bona-fides," 7, Liverpool-street, Euston-road, W.C.

Death Vacancy.—South Coast.— An excellent Nucleus of a good-class private PRACTICE for immediate disposal. Only established a few months and is now doing at the rate of £200 per annum, with every probability of two valuable appointments being secured. A Branch Surgery in connexion with the above can also be purchased if desired. Good corner house, newly decorated, rent £50. Premium, to include furniture (nearly new), drugs, and instruments, about £250.—Address, No. 1427, THE LANCET Office, 423, Strand, W.C.

Qualified Assistant wanted in manu- facturing town, Yorkshire. Single. Indoor. To commence duty at end of January or beginning of February. There is time for reading and hospital practice (60 beds), and little nightwork. Must sign usual bond. Photo, testimonials, and salary required to be sent to Dr. K., care of Brady and Martin, Chemists, Newcastle-on-Tyne.

Locum Tenens supplied on short notice. Apply to G. B. Stocker, Esq, Secretary, Medical &c. Assn., Ld., 8, Lancaster-place, Strand, W.C. The rule of the Association is that no Assistant or Locum Tenens shall be recommended till direct inquiries have been made as to his antecedents. Names of the Committee of Management and Medical Advising Board and descriptive pamphlet on application.—Telegraphic Address, "Triform, London." Telephone 1854 Gerrard.

To Medical Men requiring Assist- ANTS or LOCUM TENENS.—Mr. THOMAS RHODES, 99, Strand, W.C, who is thoroughly conversant with all requirements, has opened a New Agency where Reliable Qualified Men can be quickly obtained without fee to Principal. TRANSFERS or PARTNERSHIPS arranged at about half usual terms. Particulars free.

M.R.C.S., L.R.C.P., L.S.A., desires good out-door ASSISTANCY, preferably permanency, with prospect of working into Partnership. London or South Coast preferred. Advertiser is married (without family), experienced and reliable, and accustomed to sole charge. Good references. Would take Locumcy in meantime.—Address, with terms, &c., No. 1418, THE LANCET Office, 423, Strand, W.C.

M.B., C.M., aged 28, married, desires ENGAGEMENT about middle or end of January. Three years' experience. Well recommended. Ride, drive, and cycle.—Salary and particulars to No. 1410, THE LANCET Office, 423, Strand W.C.

A doubly qualified Gentleman of ripe experience as Assistant and Locum Tenens is open to an ENGAGEMENT in London with time for Hospital. Last references given.—Address, stating terms, No. 1407, THE LANCET Office, 423, Strand. W.C.

Assistancy or Locum wanted, by a Gentleman, eight years' experience, country and in-doors preferred. Can ride and drive. Locum in asylum or in country practice if for some time.—Apply to H., 4, Cyprus Villas, Aldershot.

Assistant, to Manage Branch, re- quired. Light work. State age, qualifications, reference, salary. Rooms, fire, light, and attendance provided.—Address, No. 1417, THE LANCET Office, 423, Strand, W.C.

Assistant (in-doors) wanted end of January. Salary £80. State age, qualifications, and references, Dr. Cane, Peterborough.

Assistant, fully qualified and un- married, wanted on a three years' agreement for a first class private and official Practice in the Tropics.—Address, R. A., care of Leathwait and Simmons, 5, Birchin-lane, London, E.C.

Medical Man of some years' expe- rience wanted at once, for some months, to take CHARGE of Country Practice in south of Scotland. Liberal terms to a suitable person.—Apply to Messrs. Constable and Johnstone, W.S., 61, Frederick-street, Edinburgh.

Assistants. — Near Manchester. — Wanted, experienced qualified ASSISTANT, able to take any kind of case. Ride and cycle. Salary £150, increasing to £200, with rooms, &c.—Kent: also qualified in-door ASSISTANT. Work light. Salary £100, with board, lodgings, &c.—For further particulars, apply, Secretary, Manchester C., Medical & Scholastic Assocn., Ltd., 8, King-street, Manchester.

Established 1839.

THE

PERFECTION OF SCOTCH WHISKEY.

For a long series of years we have devoted much attention to the selection of the finest of Scotch Whiskies and to their thorough maturing, as these, when skilfully blended, produce a **Liqueur** which is at once

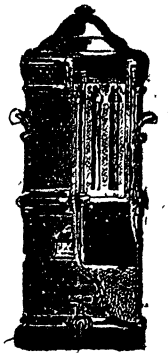
PURE, DELICATE, and HEALTHFUL.

In the knowledge of its perfect purity, we with unfaltering confidence recommend it to all who are in search of a pleasing and wholesome stimulant.

THE LANCET, after analysing our whiskey, said:—

"It is excellent in every respect, smooth in taste and delicate in flavour."

Price FORTY-ONE SHILLINGS per DOZEN,



Inclusive of Bottles and Case, and Carriage paid to any Railway Station in England in quantities of Two Dozen.

A SAMPLE WILL BE SENT PER POST ON RECEIPT OF SIX STAMPS.

DOUGLAS & MASON,

DISTILLERS & WINE MERCHANTS, EDINBURGH.

THE PASTEUR CHAMBERLAND FILTER.

The only Filter proved to afford Protection against Water-borne Disease.

This statement is made on the results officially recorded of the use of over 200,000 since 1888, which are confirmed by all Laboratory experiments. A précis of the evidence will be forwarded on application.

Made to give any required supply either with or without pressure.

THE EQUIFEX DISINFECTION APPLIANCES.

(GENESTE-HERSCHER, &c., PATENTS.)

STEAM STOVES.—The only stoves complying with the Recommendations of the International Sanitary Congress (Budapesth, 1894). Only Medal, Sanitary Institute Congress, Liverpool, 1894; Only Highest Award wherever exhibited.

SPRAYERS—Cost a fraction of the time and expense required in use of SO^2, render disturbance of inmates unnecessary, and disinfect with certainty. Exclusively used by the Municipality of Paris and elsewhere.

PARTICULARS OF OTHER APPLIANCES ON APPLICATION.

SOLE LICENSEES AND MAKERS:

J. DEFRIES & SONS, Limited, Sanitary Dept., London, E.C.

MEMBERS of the PROFESSION are CORDIALLY INVITED to WRITE for SAMPLES.

Fry's
PURE CONCENTRATED
Cocoa.

The Medical Press, including "The Lancet," "Brit. Med. Jour.," and the "Medical Annual," testifies to its **ABSOLUTE PURITY.**

THE "STRONGEST & BEST" COCOA.

FRY'S MALTED COCOA.

"Excellent. Its dietetic and digestive qualities are beyond dispute."—THE LANCET.

250 GOLD MEDALS, &c.

FRIENDS—OLD and NEW.

B. & P.'S "PATENT" CORN FLOUR. An Old Friend of 40 Years' Standing.

For light and delicate puddings, blancmanges, custards, jellies, sponges, and a host of tempting and delicious dishes. But if the best results are to be obtained every precaution must be taken to secure that only B. & P.'s is delivered—or something else may be sent instead.

B. & P.'S PAISLEY FLOUR. A New Friend of Great Promise.

By its help the delights of the tea-table are increased, by the easy addition of dainty and tempting tea cakes and scones; all kinds of home-baking are assisted and simplified, and everything made light and digestible. "Even a tyro need never fail in baking if PAISLEY FLOUR be used."

SOLE MAKERS — **BROWN & POLSON.**

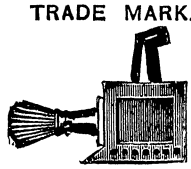
BULLOCK'S PEPSINA PORCI.

DOSE—2 to 4 GRAINS.

ACID GLYCERINE OF PEPSINE

DOSE—1 to 2 DRMS. **(BULLOCK).**

In this preparation advantage has been taken of the solubility of Pepsine in Glycerine to produce a convenient and desirable *liquid form* of this valuable medicine; whilst the preservative qualities of the menstruum confer upon the Acid Glycerine of Pepsine the property of keeping for any length of time.



May be prescribed with most substances compatible with Acids.

In 4-oz., 8-oz., and 16-oz. Bottles, and in Bulk.

The published experiments of G. F. DOWDESWELL, Esq., M.A.Cantab., F.C.S., F.L.S., &c., Dr. PAVY, Professor TUSON, the late Professor GARROD, Dr. ARNOLD LEES, and others, conclusively demonstrate the excellence, high digestive power, and medicinal value of the above preparations.

WATERS.

ABSOLUTELY NATURAL! EVERY BOTTLE FILLED AT THE KRONTHAL SPRINGS.

Sole Importers: SCHWEPPES Ltd.

Messrs. SCHWEPPES Ltd. have pleasure in notifying the Medical Profession that they have secured the sole agency for the importation of Kronthal Waters into the United Kingdom.

After full enquiry and numerous experiments Messrs. SCHWEPPES Ltd. are of the opinion that the Kronthal Natural Mineral Waters are unsurpassed by any other waters imported, for use as follows—viz.:

BLUE LABEL.

A DELICIOUS TABLE WATER.

May be drunk plain, and especially adapted for blending with WINES and SPIRITS, LEMON SQUASHES, FRUIT ESSENCES, CHAMPAGNE, and other Cups.

RED LABEL.

A Most Palatable, Highly Mineralised Water.

EFFECTS THE ELIMINATION OF URIC ACID FROM THE BLOOD.

Laboratory experiments prove that Kronthal (Red Label), is a distinct solvent of Uric Acid and gouty deposit.

KRONTHAL (Red Label) DISSOLVES SIX TIMES AS MUCH URIC ACID as Pure Distilled Water.

GREEN LABEL.

An Exceptional Iron Water.

INVALUABLE IN CASES OF ANÆMIA AND CHLOROSIS.

Contains Iron in a very valuable, because easily assimilable, form. Its administration secures the same improvement in bloodless conditions as the well-known Blaud Pill used so largely by the Medical Profession.

THE LANCET says:—Our analysis established the purity of these waters."

For Price List and particulars apply to THE SOLE IMPORTERS—

SCHWEPPES LTD., LONDON, W.

Export Enquiries—KRONTHAL COMPANY, Ltd., 53, Berners Street, London, W.
